INSTRUCTIONS

PHS policy requires that grantees submit a "terminal progress report" (final report) within 90 days after completion of the grant-

Please complete this series of items as this final report. The report will be filed with your applications, reports and other grant business in NIMH's cantral files. It will be read by staff in resserch program areas, and may be read by other institute staff concerned with program analysis, communication, evaluation and planning. The report will be used for information about your research, i.e., to describe and summarize the information (procedural as well as substantive) resulting from NIMH support, and to relate that information to mental health-problems and research. Your report will often be used apart from your application; however, other documents, such as publications and applications, will be available from the project file if needed.

These-guidelines have-been designed with relatively small response spaces to encourage brevity. However, do not nestrict your response if more space is needed: be complete, using additional labeled pages inserted where necessary (sample page included). Extensive descriptions and discussions, if desired, should be made in addition to your summary response to the item, and should be placed as appendices. Discussions of issues not covered by these guidelines are also welcome as appendices. Use clear, concise language, avoiding highly technical language where practicable (this will vary for different types of research); appendices could be more technical than responses to the items.

All publications resulting from this project, and not previously submitted, should be submitted with this report (or as soon as available); see the section on Dissemination. Publications should not be used in lieu of responses to particular items.

Send copies of this	report and all appendices as indicated below.		FOR HIMM USE ONLY

Describe the methodology used in your research, including characteristics of any sample used:

CONDUCT OF RESEARCH:

A comprehensive review of the methods and procedures used in the study is presented in the attached continuation pages titled, "Method." The documentation from the United States Department of Education, "Fall Enrollment and Compliance Report of Institutions of Higher Education, 1980 (FECR Survey, HEGIS XV), that was used to develop the sample is included as Appendix A.

10. Did you have significant technical methodological difficulties? (Examples: necessary measurement tools undeveloped; unexpected inadequate data base) If yes, describe, and explain how you dealt with them.

1 Yes 2 🖾 No

Did you have significant practical operational difficulties? (Examples: trouble with equipment; loss of sample or data; difficulties with cooperating

1 X Yes

If yes, describe, and explain how you dealt with them.

2 | No

(22)

The primary difficulty encountered was resistance to participation in the study. The use of the Ms. identification and members of the Ms. Foundation Board as personal contacts were insufficient to counter the degree of resistance encountered. Personal campus visits, letters of support from nationally known clergy, and calls to local colleagues, friends, and women's studies personnel were used to deal with the resistance. Eventually, 33 schools were recruited for participation, somewhat short of the 50 that were proposed. However, time and financial limitations precluded continued

	(28) Opening up a new line of research (30) 2 Providing facts ready for application
IMPLICATIONS:	(29) UContributing to the knowledge base in a field
	of the field (31) Indicative of a "dead-end" line of pursuit
4	
	17. Do you have immediate plans for further research in this area?  1 🖾 Yes (32)
	If yes, describe: 2 □No
	Currently, I am working on a project funded by the National Institute of Justice called, "Criminal Victimization: The Somatic Impact of Psychological Stress. Six questions on the prevalence and somatic impact of criminal victimization are being studied by self-report questionnaire, interview, and medical chart review in 5,500 members of a prepaid health plan.
	In addition, I would like to pursue funding to undertake further analyses of the data set that is described in this report.
•	
	18. Beyond your own plans, what is your opinion of the future directions this research area should take?
	Because college students represent approximately 35% of the population aged 18-25, they were an important group to study. However, the next step is to extend the research into the general population. Such studies would include a greater age range of subjects and would allow conclusions regarding the incidence of sexual aggression throughout the life span. Knowing whether or not sexual aggression lessens as people mature and gain experience has important preventive implications. Secondly, the results of the present study raise questions regarding the course of spontaneous resolution of rape among hidden victims. Currently, little is known regarding the immediate and long-term cognitive impact of sexual assault, nor the spontaneous processes of cognitive re-appraisal and coping through which the trauma is eventually dissipated. Research on this topic would have important therapeutic implications.
	S.
	19. Do you have specific suggestions (experiments, cautions, etc.) for other research in this area?
	If yes, describe: 2 □No
	In all my research to date, I have failed to anticipate the degree of resistance to be encountered. Obtaining access to 33 higher education institutions required 15 months while obtaining access to a medical population required 8 months. The topic of sexual victimization is deeply emotional and difficult for many people to discuss. Administrators who control research access often feel that the persons under their charge must be protected from the traumatic impact of a rape study. Future researchers must be aware that research access may not be achieved easily. Ample time must be anticipated to allow initial anxiety to dissipate among potential institutional participants. In addition, the researcher must be prepared to submit more thorough documentation than is usually necessary, and to be flexible regarding changes in procedures so that fears about the study impact may be allayed.

:	GRANT NUMBER: RO1-MH-31618
IMPLICATIONS	20. Are you aware of other researchers using your techniques, or planning to replicate your study, or of some individual or organization continuing your work? If yes, describe, and check the type of impact which best characterizes the impact of your research at this time.  1  Yes 2  No (34) Specific utilization (35)
(Centinued)	First, some of the concepts developed in research on college students (e.g., acknowledged and unacknowledged rape) are being incorporated into research by other investigators. Second, the specific methods developed in the study are being applied on numerous campuses. I have received over 150 requests for publications and copies of the survey. The goal of many of these requests is to conduct studies to establish the local extent of sexual aggression in order to raise consciousness and document the need for prevention and assistance services.
	21. As an appendix, list all publications (and articles accepted for publication) resulting from this project. Send any publications which have not already been submitted as appendices, with grant number indicated on each. (See instructions, page 1, regarding submission of books)
	22. Do you have any plans for future publications, papers, and/or demonstrations dealing with the results of this project? If so, describe briefly. Send in any future publications based on this project as per instructions on page one.
DISSEMINATION:	I plan to disseminate the results through professional journals. As time allows, the data set will support at least the following publications:  (1) a summary of the incidence and prevalence data for both men and women  (2) a report of the variables that differentiate sexually aggressive men from nonsexually aggressive men
	<ul> <li>(3) a description of the variables that differentiate sexually victimized women from nonsexually victimized women</li> <li>(4) an account of the variables that predict those women who label a victimization as rape</li> <li>(5) a statement of the role of child sexual abuse in the prediction of adult sexual aggression and adult sexual victimization</li> <li>(6) a review of the childhood, psychological, and assault variables that predict the traumatic impact</li> </ul>
	of sexual victimization  23.(7) The Built of Para profile negotial free high hiber political and reflection in Sex spective been submitted for publication but not yet published, contents of the report 1 Yes will, as far as possible, be held as restricted information for six months unless the investigator agrees to an earlier release. Do you request this restriction?
APPENDICES:	See instructions, page 1, paragraph 3.
	LIST OF APPENDICES
	APPENDIX A: Documentation From U.S. Department of Education on which sampling plan was based

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 9. (Methods)

#### METHOD

The specific aims of the present study were the following:

(1) To establish that college students are a high risk population for rape and other forms of sexual aggression through collection of prevalence and incidence data in a nationally representative sample:

(2) To develop a descriptive data base obtained from both hidden and identified subjects that included background variables, experiences with sexual aggression and victimization, psychological characteristics, current behavior, and assault impact;

(3) To determine whether sexually aggressive men and sexually victimized women can be differentiated from comparison samples of nonsexually aggressive men and nonsexually victimized women; and.

(4) To describe the emotional impact of acquaintance rape upon the victim.

These goals were addressed through administration of a self-report questionnaire to a national sample of 6,104 students in U.S. institutions of higher education. The methods of sample design, institutional recruitment, questionnaire construction, validity and reliability checks, administration procedures, variable scoring, data reduction and data analysis through which these goals were addressed are described in the following sections.

## Sampling Plan

The sampling goals of the project were to represent the universe of the higher education student population in the United States in all its diversity—males, females, technical schools, community colleges, Ivy League schools, state universities, and so forth. Since it appeared possible that experiences of sexual assault, both among perpetrators and victims, would vary among schools located in SMSA's or rural areas, or between sex-balanced schools and predominately women's colleges, it would have been a mistake to recruit a sample of only those schools at which "network" contacts could be helpful in gaining access. It was unlikely that this procedure would have resulted in a sample that reflected the desired institutional diversity.

No sample design could be expected to result in a purely random or representative sample, however, because the subject matter is sufficiently controversial that some schools targeted by a systematic sampling method can be expected to refuse to participate. For example, both small privately funded religious schools or schools where political reactions among students are encountered might be predicted to refuse participation. Thus, the object of the sampling procedure was to produce a final sample that would be as representative as possible and free from \*\* distortions introduced by selective recuritment by the project directors or selective participation by institutions.

#### Initial Decisions

Several decisions were made that governed subsequent decisions. First, the commitment to replicability and representativeness meant using as a sample frame all of the institutions of academic post-secondary education in the United States. Second, it was concluded that

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

9. (Methods)

administration of the instrument had to be conducted on-site and not by mail. The latter would have produced a strong self-selectivity bias. On-site administration in classrooms was considered to produce a more reliable representation of those asked to complete the survey. Of course, completion of the form was voluntary. However, administration in the classroom with a project representative present rendered participation convenient, controlled, and as safe as possible. Third, it was determined that on-campus administration should not be conducted only in those classes in which the instructor would be most likely to cooperate (i.e., psychology, sociology) since this procedure could result in an unknown bias toward certain kinds of students. Instead, the sample had to be drawn from the diversity of offerings within each institution. These requirements dictated that the sample be selected in stages. The first stage was the selection of institutions. The second stage was the selection of classes within institutions.

#### Selection of Institutions

The United States Department of Education (Office of Civil Rights) maintains records of the enrollment characteristics from 3,269 institutions of higher education in the United States. This office provided a copy of their information for 1980 (the latest available) on data tape to the survey consultants, Clark/Jones, Inc. of Columbus, Ohio. The documentation for the data tape is found in Appendix A.

The information includes extensive profile data on institutions of higher education. Using this file, homogeneous clusters of institutions were developed according to six criteria:

- (1) location in or outside of an SMSA of certain sizes
- (2) enrollment above or below the national mean percentage enrollment of minority students
- (3) control of the institution by private secular, private religious or public authority
- (4) type of institution including university, other 4 year college, and two year institutions
- (5) location in the 10 United States Department of Education regions of the United States
- (6) total enrollment within five levels of approximately equal numbers of students

Using these criteria, the institutions of the entire nation were divided into homogeneous clusters within regions. For example, all four year institutions located in New England, having below average minority enrollment, controlled privately, and located outside of an SMSA constituted a homogeneous cluster. Two sampling rules to select the schools to be recruited into the sample were developed. First, the largest institution in each region was always included. Without this rule, it would have been possible to omit the "Big Ten" or other major schools from the sample entirely. Second, every xth cluster was sampled in proportion to the enrollment of the region. The number of institutions that were proposed from each cluster are presented in Table 1. From the homogeneous cluster, replacements were sought if the original target school proved uncooperative. The final sample was the result of an interplay of scientific selection and head-to-head negotiation but within the limits of substitution rules requiring replacement within homogeneous clusters. Of the 50 schools originally contacted, 30 refused to participate and were replaced by other schools within the cluster. Thus, the integrity of the sample was maintained.

DESCRIPTIVE CHARACTERISTICS:

R0	1 - MH - 3	16	18

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 9. (Methods)

Several exceptions to the sampling rules were made for the sake of reasonableness and cost constraint. First, military schools were omitted because it was felt that the type of information sought would place students in conflict with their military code. Also, previous experience had suggested that military permissions are very difficult to obtain. Second, schools with enrollments under 1,000 were eliminated. There are approximately 1,000 such schools. Travel to them for exceptionally small sample numbers was not cost effective. Third, schools not in the contiguous United States were eliminated because travel funds were not sufficient. Finally, graduate schools were eliminated because post-graduate students were not intended as part of the sampled universe.

## Institutional Recruitment

The procedures for obtaining institutional cooperation began by identifying the responsible individual in the central administration. This individual was first contacted by telephone by an assistant selected from among aplicants with professional experience in public relations. The initial telephone contact was followed up with a mailing of information. A copy of the information package is found in Appendix B. If the administrator needed further information, he or she was contacted by the Principal Investigator. Mostadministrators were unwilling to make a personal decision about participation. In virtually every case, the proposed project was placed before a committee for decision. To enhance institutional cooperation, letters of support were obtained from the directors of education of the major religious demonimations and from women clergy who work in the area of sexual abuse. In addition, personal campus visits were made by the staff of Ms. Magazine, and members of the Ms. Board of Consultants intervened personally when possible. When a campus had a Woman's Studies Program, the assistance of the director was solicited.

If administrative clearance was obtained to pursue the research, a signed "Permission for Institutional Access" form was obtained from every participant institution. Documents were then submitted to the institution's Human Subjects Review Board. While the project technically qualified for expedited review because respondents were completely anonymous, most institutions felt that the project was sufficiently controversial to require a full review. In many instances, two or more meetings of the institutional review boards were required to satisfy all objections. Because of the large number of vacation breaks in the academic calendar, the amount of time required to obtain a decision from the institutions became very extended. Some schools required 15 months to arrive at a final decision. During that period, 93 schools were contacted and 33 institutional participants were obtained. Twenty of the institutions were first choices, the remaining 13 were solicitated from among 43 replacements. A signed "Human Subjects Review" was obtained from every participant institution. The institutional participants are listed in Table 2. (Note: This table is not for public distribution. Institutions were quaranteed anonymity).

It might be argued that the resulting sample would be biased toward those schools with a "liberal" administration. However, this did not prove to be the case. Perusal of Table 3 which lists the institutions who refused to participate and their reasons reveals that some schools with the most liberal reputations in the nation refused while others with a presumed conservative bias cooperative. It should be noted that the reasons for nonparticipation given by prestigious institutions were no more sophisticated than the reasons given by less elite institutions and in some cases were less informed. The final sample of institutions was as

## TABLE 3

# Institutions that Declined Participation and their Reasons

1.	Atlantic Christian College	It is a religious school and the president doesn't want to begin his term with a controversial study.
2.	Berea College	It was felt that the responses from students could be identified and studied.
<b>3.</b>	Belmont College	It is a Baptist school which receives many requests for surveys. They say no to all.
4.	Blue Mountain Community College	College Affairs Committee questioned the need for the study.
<b>5.</b>	Brandeis	The study would be taken out of context and was of a sensational nature. There was no one on campus to provide continuity weeks after the survey was administered. Brandeis students are highly intellegent and therefore are less likely to do behavior of this sort than students of lesser ability like they have at places like University of New Hampshire.
6.	Brigham Young	No reasons.
7.	Bunker Hill Community College	The study is an invasion of privacy, it will cause bad publicity, it requires too much faculty time, and they have not had any episodes of rape on their campus.
8.	University of California, Berkeley	The purpose of the study and the hyptheses are not clear, the methodology is bad, the survey would cause bad publicity, and the survey is misleading and slanted. The questionaire itself is sexist, racist, homophobic, misogynistic, and anti-men. No forseeable benefit to Berkeley students.
<b>9.</b>	California State University	The survey doesn't provide the information necessary for informed consent, there is a risk to offenders and victims because the follow-up counseling is inadequate, no local personnel are involved, and their is a lack of full disclosure.
10.	Cape Fear Technical Institute	They are involved in other studies and are busy with re-accreditation.
11.	Chattachoochee Valley Community College	No reasons.
12.	Coe College	They can't invest the time.

13.	University of Colorado	Research not allowed in classrooms.
14.	Dillard University	Religious objections.
15.	East Carolina University	No reasons.
16.	Eastern Kentucky University	University of Kentucky does all the research allowed on their campus.
17.	Feather River College	No reasons.
18.	Florida Institute of Technology	Administration opposed.
19.	Framingham State	No reasons.
20.	Gardner-Webb	No reasons.
21.	Greater Hartford Community	They don't want to get involved in surveys.
22.	Harvard University	While they found the study fascinating, they must protect Harvard students because "everyone wants to survey Harvard students and that is not what they are here to do."
23.	Hampton Institute	Black schools could be too easily identified.
24.	Hopkinsville Community College	It's in the Bible belt and they have ongoing studies that duplicate the survey.
25.	University of Houston	Human Subjects Committee denial.
26.	Jefferson Technical Institute	Religious students, parents, and taxpayers might object and the school is operated by tax levy. Thus the study could affect voters.
27.	Joliet Junior College	Human Subject Committee denial.
28.	Junior College of Albany	No reasons.
29.	Lee College	Conservative and they have had no problems.
30.	Marygrove College	They have had 12 current cases of date rape and the study could be confused as a betrayal of victims' confidence in the faculty members who were told.
31.	Mass. Bay Community College	New president is busy with other things.
32.	McHenry County College	Survey overly intrusive, biased, and based on preconceptions.

33.	Miami-Dade Community College	Survey is too complicated for the ability level of their students and the college is already participating in another similar study.
34.	MIT	They recently did a sexual harassment survey. Two surveys is so short a time would be against the student's welfare. Also, MIT students work hard and
		the survey would add to their stress. Finally, they have only 20% female students so the survey isn't that relevant to the school.
35.	Monroe County College	Survey too long.
36.	Montclair State College	Can only be done in psychology classesregistrar has been ordered not to cooperate.
37.	Morris Brown College	Don't want to get involved.
38.	Northern Nevada Community	Lack of interest in the topic.
39.	Northwood Institute	They are too young a school.
40.	Parsons School of Design	They are doing their own studies.
41.	Pepperdine University	Anything connected with sex is unChristian in many minds.
42.	University of Puget Sound	The survey lacks sophistication. The post-masters
· ·	oniversity of rager obtains	level experimenters should give counseling. They
		won't put students into a situation where painful
		feelings are elicited but not dealt with therapeutically.
		Also, the use of terms like "sexual misunderstanding"
		pertetuate the norm that rape shouldn't be discussed.
		The study is based on an inadequate understanding of
		the research on acquaintance rape.
43.	Ogelthorpe University	They are conservative and do not want the survey on
,		campus. Ms. is not a good magazine.
44.	Oklahome City University	No reasons.
45.	Southern Ohio College	Students are "traditional, unsophisticated, and
		emotionally insecure enough to find the questionnaire offensive and invasive of their privacy."
46.	Seattle University	No survey allowed in classes.
47.	Spokane Falls Community College	Human Subjects disapproval.
48.	Taylor University	They are "evangelical" and the subject is disturbing.

49.	University of Tulsa	Human Subjects disapproval.
50.	University of Texas, Austin	No research allowed in classrooms.
51.	Victoria College	They are "in the Bible belt and are conservative."
52.	University of Washington	No research allowed in classrooms.
53.	Western Conneticut State University	Financial difficulties.
54.	Western Kentucky University	They emphasized that the reason they were saying no was NOT because they are a religious school.
55.	Wilkes Barre Community College	Other commitments.
56.	Yale	No surveys allowed in classes and no other viable alternative to administration. Stated that Yale is so unique that procedures developed elsewhere would not work.
57.	University of Kansas	No reasons.
58.	Wellesley College	Administrative changes and changes in membership of Human Subjects Committee. Three different statements to the Human Subjects Committee and modifications in procedures still resulted in Human Subjects disapproval.
59.	Harrisburg Area Community College	Withdrew at last minute. No reasons.
60.	University of New Mexico, Gallup	Faculty opposed.

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 9. (Methods)

replicable and representative a sample of of postsecondary institutions in the United States as it was possible to obtain within time and budgetary limitations and given the nature of the inquiry. While sampling error cannot be measured precisely with a sample of this type, representativeness can be tested by reference to other data sources.

#### Selection of Classes

From each participant institution a class schedule was obtained. From that class schedule, a random selection process was used to choose subject classes and alternates in the case of schedule conflicts or refusals. The only limitations on class selection were that classes under 30 students and large lecture sections were eliminated. These limitations were necessary to insure that one experimenter's time on a campus was used efficiently while avoiding classes that were too large for one person to handle. The target number of classes was 4 in smaller schools and 16 in larger schools. The actual number of classes visited was 7 at smaller and medium sized schools and 12 at major universities. Instructors of the targeted classes were contacted by telephone by a research assistant. The telephone call was followed up by a mailing of information regarding the study if the instructor requested. Instructors were asked for permission to administer the survey during a specific class period. They were further requested to tell the students nothing about the project and not to be present during the administration. It was felt that greater standardization of testing conditions could be schieved if the project personnel presented the description of the survey to students. Furthermore, it was felt that the instructor's presence could be coercive upon students to participate.

## Subjects

The final sample consisted of 6,104 persons including 3,187 women and 2,971 men students. The specific demographic characteristics of the participants are summarized in Table 4. The 3,187 woman participants were characterized as follows:  $\underline{M}$  age = 21.4; 85% single, 11% married, and 4% divorced; 86% White, 7% Black, 3% Hispanic, 3% Asian, and 1% Native American; and 39% Catholic, 39% Protestant, 4% Jewish, and 20% other or none. The 2,971 male participants were characterized as follows:  $\underline{M}$  age = 21.0; 87% single, 9% married, 1% divorced; 86% White, 6% Black, 3% Hispanic, 4% Asian, and 1% Native American; and 40% Catholic, 34% Protestant, 5% Jewish, and 22% other or none.

#### Comparisons with National Enrollment Data

Four variables were considered to determine the extent to which this sample was representative of U.S. higher education enrollment: institution location and region, subject ethnicity and income. A comparison of the present sample and the U.S. higher education enrollment is presented in Table 5. Whereas the data on the present sample were collected in 1984-85, the most recent information available on institution location and region is 1980 (U.S. Department of Education, Fall Enrollment and Compliance Report of Institutions of Higher Education, 1980). The most recent information on the ethnicity and income of students is 1982-1983 (Statistical Abstracts of the United States, 1985, p. 152, Tables # 252 and #254). These latter data, particularly, could be expected to have changed somewhat as a result of recent changes in federal policies governing student financial assistance. Nevertheless, the present sample is a very close approximation of the higher education enrollment in terms of institution location, student ethnicity, and student family income.

GRANT NUMBER RO1-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 9. (Methods)

The only variable on which significant discrepancy is noted is region of the country. The present sample somewhat overrepresents the Plains States and greatly underrepresents the West. These discrepancies reflect irremediable difficulties in obtaining institutional access to some locations. For example, in the West a personal visit was made by a member of the Ms. staff to an institution, the efforts of the Affirmative Action Director of the California State University System were enlisted, a prominent member of the clergy made personal calls to several private schools, calls were made by the Principal Investigator to the Women's Studies directors at target schools, and special re-reviews were obtained at two major California universities. A total of 12 schools in the West were solicited and each was given extensive personal attention. In spite of these efforts, after 15 months of time only 3 institutions had agreed to allow data collection. In order that the success of the entire project not be jeopardized, it was decided to proceed with data collection without full representation from western schools.

#### Weighting the Data

The regional disproportion is unimportant in many respects since even without extensive sampling in the West, the individual participants in the sample were still reflective of national enrollment in terms of ethnicity and family income. Nevertheless, for purposes of calculating the incidence and prevalence data, weighting factors were used. The two major disproportions are the inclusion in the final sample of more than the desired numbers of students from Plains States schools and fewer than the desired number from the West. The present sample was weighted using the proportions of enrollment in each of the federal regions. These data are found at the bottom of Table 5. Whereas 14.4% of the present sample came from the Plains states, only 7.4% of the national enrollment is represented by that region. Thus, the repsonses from students in the Plains region were weighted to be equivalent to 7.4% of the present sample. Likewise, only 4% of the subjects in the present sample were attending western schools whereas 18% of the nationwide enrollment is in the west. Therefore, the responses from subjects in the west were weighted to be equivalent to 18% of the present sample. Later, both weighted and unweighted prevalence figures will be presented. The effect of weighting was very small and was in the direction of rendering the final estimate of prevalence more conservative.

#### Questionnaire Construction

All data were obtained via a self-report questionnaire titled, "National Survey of Inter-Gender Relationships. This title was selected to be neutral and to avoid the word "sex" so that participants didn't prejudge the content of the survey before explanations were given. However, the inside coversheet of the questionnaire described the content explicitly. A copy of the questionnaire and coversheet is found in Appendix B. The questionnaire consists of approximately 330 questions divided into seven sections and has a branching format. Those subjects who have not been involved in sexual aggression are instructed to skip the sections relevant to those experiences. The specific content of the questionnaire was as follows:

Item No. 9. (Methods)

#### Section A

This section contains 7 questions regarding the participant's demographic characteristics.

#### Section B

This section contains 26 questions regarding the participants social history and current behavior. Included are questions regarding early family stability, parental strictness, family violence, delinquent involvements, history of psychological disturbance as reflected by suicide attempts and psychotherapeutic treatment, drinking habits, use of pornographic magazines, participation in sexual oriented discussions of women, sexual values, number of sexual partners, sexual satisfaction, and quality of relationships. The selection of background questions was guided by a review of relevant literature on the etiology of sexual assault (e.g., Ageton, 1983; Amir, 1971; Check & Malamuth, 1983; Finkelhor, 1979, 1984; Koss, Leonard, Beezley, & Oros, 1985; Tsai, Feldman-Summers, & Edgar, 1979).

#### Section C

This section contains the 10 items that compose the Sexual Experiences Survey (Koss & Oros, 1982; Koss & Gidycz, 1985). This survey has been described as a self-report instrument that is designed to reflect various degrees of sexual aggression and victimization and is capable of identifying hidden rape victims and undetected offenders. Internal consistency reliabilities of .74 (women) and .89 (men) have been reported (Koss & Gidycz, 1985). The test-retest agreement rates between administrations one week apart was 93% (Koss & Gidycz, 1985).

Validity has also been studied. The Sexual Experiences Survey was administered in university classes and 1-4 months later the items were re-administered privately by a trained interviewer to explore the accuracy and truthfulness of self-reported sexual experiences. The Pearson correlation between a woman's level of victimization based on self-report and her level of victimization based on responses as related to an interviewer was .73 (g<.001). The Pearson correlation between a man's level of aggression as described on self-reports and as given in the presence of an interviewer was .61 (g<.001). However, the authors noted that these figures may underestimate the validity of the Sexual Experiences Survey since the correlations were calculated between two different administration formats (self-report and interview) on two occasions separated by several months. They noted the need for a study in which the survey is administered in both formats on the same occasion. This study was performed as part of the present project and is discussed in a forthcoming section.

#### Section D

This section contains 26 questions (male version) or 35 questions (female version) that explore the the most serious level of sexual aggression the individual reported. If more than one instance of that level of aggression has occurred, the respondent is asked to focus on the experience that is best remembered. Questions involve the context of the assault (number of perpetrators, relationship of victim and offender, degree of acquaintance, prior intimacy), situational characteristics of the assault (man's or woman's "turf," on or off campus, drinking or drugs involved, social situation surrounding the event, emotions experienced at the time), severity of the assault (types of force used by the man, forms of resistance used by the

GRANT NUMBER RO1-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

. (Methods)

woman), and post-assault behavior (who was told, how they reacted, how they labeled the experience, whether it is expected to happen again). The content of this section was guided by a review of the clinical literature on the impact of rape (e.g., Atkeson, Calhoun Reskick, & Ellis, 1982; Davis & Friedman, 1985; Ellis, 1983; Frank & Stewart, 1983; Holmes & Lawrence, 1983; Kilpatrick, Yeronen & Resick, 1979; Koss, 1985; McCahill, Meyer, & Fischman, 1979; Notman & Nadelson, 1976; Ruch & Chandler, 1980; Russell, 1984; Sales, Baum, & Shore, 1984).

#### Section E

This section was contained different psychological measures for men and for women. For men, the primary goal was to include psychological measures relevant to the major theoretical models of rape including the psychopathology model (Groth & Birnbaum, 1979) and the social control model (Weis & Borges, 1973; Feild, 1978; Koss et al., 1985). Thus, male respondents were administered the 28 items of the short form MMPI Psychopathic Deviate Scale (Graham, 1977, p. 247). This scale has been shown in previous research to be elevated among incarcerated rapists and other criminals (e.g., Radar, 1977). In addition, male respondents were asked to answer the 30 item Hostility toward Woman Scale (Check, 1984; Check & Malamuth, 1983).

For female participants, the major goal towards which standardized psychological tests were directed was to examine the impact of sexual victimization. Because depression and rape related anxiety are two major aftereffects of sexual victimization (e.g. Frank & Stewart, 1983, Kilpatrick & Yeronen, 1979), women were asked to respond to the Beck Depression Inventory (Beck, Ward, Mendelson, Mock, & Erbaugh, 1961) and the State-Trait Anxiety Inventory (Spielberger, Gorsuch, & Lushene, 1970).

The Beck Depression Inventory consists of 21 items which are believed to reflect symptoms and attitudes of depression. Reliability data have been reported in several studies (e.g., Beck et al., 1961; Beck, 1967, Gould, 1982). The Spearman-Brown split-half reliability was .93. Internal consistency reliability was .82. Test-re-test reliability has rangaed from .60-.83 (Hatzenbuehler, Parpal, & Matthews, 1983). Correlations of .65-.67 have been reported in studies of the relationship of the score on the Beck Depression Inventory and clinical ratings of depression (Beck, 1967).

The State-Trait Anxiety Inventory contains both a trait and a state scale of anxiety. Only the trait scale was used in the questionnaire. Trait anxiety refers to relatively stable individual differences in anxiety proneness. The Trait Scale is considered to be useful as a screening device for students to determine the extent to which they are chronically troubled by anxiety. The Trait Anxiety Scale consists of 20 items. Internal consistency of the scale is supported by alpha coefficient that range from .86-.92 among several different normative groups (Spielberger et al., 1970). Test-retest correlations ranged from .73-.86. Correlations among the Trait Anxiety Scale, the Taylor Manifest Anxiety Scale, and the IPAT Anxiety Scale range from .75-.83 for both college students and patients (Spielberger et al., 1970). The State-Trait Anxiety Inventory has been shown to distinguish rape victims from nonvictims for at least one year postrape (Kilpatrick & Yeronen, 1984).

GRANT NUMBER ROI-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

9. (Methods)

#### Section F

This section contains items about sexually abusive experiences before the age of 14. Item 1a-h contains the screening questions used by Finkelhor (1979) in his survey research on early sexual abusive experiences of college students. The remaining items in the section request more detailed information about the abusive experience. Respondents are asked to refer to the highest severity experience in answering the questions. If they have been victimized more than once at that level of severity, they are asked to think of the most significant experience. The questions cover the context and severity of the child abuse (age of victim, age of perpetrator, relationship to perpetrator, how many times the abuse occurred, reason the victim participated), and post-abuse behavior (who was told, how they reacted, negative emotions at the time, victim label for the experience).

#### Section G

This section contains the 36 items developed by Burt (1980) to measure the extent to which an individual endorses a set of rape supportive beliefs. Previous research has indicated that incarcerated offenders (Feild, 1978) as well as undetected sexually agressive men (Koss et al., 1985) are differentiated from nonsexually aggressive men by the intensity with which they endorse these beliefs. In addition, sexual arousal to depictions of rape can be predicted by an individual's degree of endorsement of rape supportive beliefs (Check & Malamuth, 1983).

#### Section H

Section H contains two standardized psychological measures. The first is the Extended Personal Attributes Scale (Spence, Helmreich, & Holahan, 1979) from which measures of positively valued masculinity, positively valued femininity, and androgeny can be obtained. The social control model of rape implies that individual differences in sex role stereotyping may affect behavior both before and after a rape has occurred (Check & Malamuth, 1983; Koss et al., 1985). Test-retest reliability is reported to be .80 after a 13 week interval. Internal consistency reliability was .73 for men and .91 for women (Spence, Helmreich, & Stapp, 1974). Correlations between the Extended Personal Attributes Scale and measures ofsex-role stereotyping, self-esteem, neuroticism, and acting out have been reported (Spence, Helmreich, & Holahan, 1979). The correlations with the Bem Sex Role Inventory were .75 for males and .73 for females on the masculinity subscale and .57 for males and .59 for females on the feminity subscale (Spence & Helmreich, 1978). Correlations with social desirability are low with coefficients ranging from .08 to .36.

Finally, this section contains the Conflict Tactics Scale (Straus, 1979). This scale contains items that describe various strategies that can be used to express anger and resolve arguments with significant others. The items include verbal behaviors (calm discussion, yelling or insults), withdrawal, noncontact physical aggression and physical aggression. However, most respondents did not have time to finish the Conflict Tactics Scale. Because of a significant amount of missing data, the data from this scale were not analyzed.

#### FINAL REPORT GUIDELINES CONVINUATION PAGE

Item No.

9. (Methods)

## Yalidity of the Questionnaire

Many investigators have questioned the veracity of self-reported sexual behavior. Concerns have been expressed that subjects will exaggerate their sexual experience and enjoy a "fantasy trip" or they may deny socially unacceptable acts. Thus, it has been suggested that subjects both overstate and understate their true behavior. A major alternative to self-report is the private interview. However, serious problems with sample attrition and selective participation have been encountered in studies that have employed an interview format (Ageton, 1978; Koss et al., 1985). Interview studies of sexual behavior usually employ a two-stage sampling procedure where a self-report survey is used to identify persons with extreme experiences with sexual aggression. Then, these individuals are re-contacted to participate in an interview. Koss et al., (1985) reported that only 25% of male subjects who responded to a survey gave their permission even to be contacted for an interview. Of those men who presented themselves for interview, 37% denied having engaged in any sexually aggressive behavior whatsoever although they had admitted such acts on self-report.

Koss and Gidycz (1985) suggest that to answer questions regarding the validity of male's self-reported sexual behavior, a study was needed in which a questionnaire was administered both by self-report and by one-to-one interview on the same occasion. This validity study was carried out during the present project. Subjects were 15 volunteers recruited through newspaper advertisments in a major university newspaper. The study took two hours of time and subjects were paid \$10 for participation. All subjects were juniors or seniors and psychology majors were eliminated from consideration. The demographic characteristics of the participants were as follows:  $\underline{\underline{M}}$  age = 21.3; 100% single; 87% white, 13% minority; 27% Catholic, 27% Protestant, 27% none or other, 20% Jewish; 40% family incomes > \$35,000. These demographic characteristics closely parallel those of the men in the national sample.

All participants received gave their self-reports on the the "Survey of Inter-Gender Relationships" first. Then, they were interviewed individually by a fully trained, licensed, and experienced male Ph.D. clinical psychologist. The interview questions included items pertaining with participants' sexual history both before and after the age of 14. The intent of these questions was to match the participants verbal responses with their survey responses. Then subjects feelings and evaluations of the survey were elicited including comments regarding: (a) the content of the survey, (b) feelings about the survey, (c) validity of responses, and (d) confidentiality and purpose of the survey.

The results indicated that 14 of the participants (93%) gave the same responses to the Sexual Experiences Survey items on self-report and in interview. The one inconsistency involved an individual who admitted a behavior on self-report which he later denied to the interviewer. The same rate of agreement (93%) was found between interview and self-report of sexual experiences before the age of 14. The one instance of inconsistency involved a different subject who indicated on self-report that he had had intercourse before the age of 14 whereas in his conversations with the interviewer indicated that he had not achieved full penetration. On average subjects rated their honesty as 95% and indicated that the reason for lack of full honesty was time pressures getting through the questionnaire. While half of the respondents indicated that they had no emotional reaction to the survey, 27% of participants stated that they felt embarrassed or nervious, 13% felt the items stimulated hurtful or sad

Item No.

(Methods)

memories and 13% felt that they experienced positive, pleasant feelings while taking the questionnaire. However, 14 or 15 respondents (93%) indicated that their feelings had not interfered with their ability to answer the questions.

#### Administration Procedures

The questionnaire was administered in classroom settings by 1 of 7 post-master's level clinical psychologists who participated in the project including 2 men and 5 women. All experimenters were trained personally by the Principal Investigator. The class instructor was not present during the administration. Questionnaires were distributed to students who were asked not to open them until directions were given. Experimenters read from a prepared script. The survey was accompanied by a coversheet that contained all the elements of informed consent. These forms as well as a copy of the questionnaire can be found in Appendix B.

Students were not asked to sign their names on the consent form because the survey was completely anonymous. Students who did not wish to participate in the survey were asked to remain in their seats and do other work. This step was taken so that persons who objected to the survey would not be stigmatized. The rate of refusal to complete the survey was negligible. Only 91 persons (1.5%) indicated that they did not wish to fill it out. After all students had completed the survey, the group was debriefed by the experimenter according to a prepared script. In addition, all students received a printed debriefing sheet that indicated where the proctor would be available for a private conference and contained phone numbers of local agencies who had agreed to answer questions or to offer services to participants. The college counseling center of every campus visited was informed of the project and invited tolist a sexual assault specialist on the debriefing sheet and/or to send observers to the survey administration if desired.

#### Yariable Scoring and Data Reduction

For purposes of data analysis, a categorical scoring system was derived to classify respondents in terms of their sexual experiences. Five classes of sexual aggression/sexual victimization were developed including: no sexual aggression or victimization, sexual contact, sexual coercion, attempted rape, and rape. On the basis of their responses to the Sexual Experiences Survey in Section C, all respondents were classified into one of these groups. Details of the scoring system are summarized at the top of Table 6 (Women) and Table 7 (Men). The groups labeled rape and attempted rape include individuals whose experiences meet legal definitions of these crimes. The group labeled "sexual coercion" included subjects who engaged in/experienced sexual intercourse-subsequent to the use of menscing verbal pressure or misuse of authority over the victim. No threats of force or direct physical force was used. The group labeled "sexual contact" consisted of individuals who had engaged in/experienced sexual play such as fondling or kissing subsequent to the use of menacing verbal pressure. misuse of authority, threats of physical force, or actual physical force. The possibility was considered of separating from this latter group those persons whose experiences involved force. However, this option was rejected because forceful instances of sexual contact represented only a small portion of the experiences (3% of women; 1% of men). These classes of sexual aggression/sexual victimization were used as independent variables in many of the analyses that will be discussed later.

## TABLE 6

#### DESCRIPTIVE YARIABLES: WOMEN

#### 1. Yictimization Groups

- A. Nonvictimized
  - No to all items 1-10 in Section C, pages 31-40.
- B. Sexual Contact

Yes to items 1, 2, or 3; no to all other items in Section C, pages 31-40.

C. Sexual Coercion

Yes to items 6 or 7; no to all other items except 1,2, or 3 in Section C, pages 31-40.

D. Attempted Rape

Yes to items 4 or 5; no to all other items except 1,2,3, 6, or 7 in Section C, pages 31-40.

E. Rape

Yes to items 8, 9, or 10 in Section C, pages 31-40.

## II. Background Characteristics

- A. Demographics
  - 1. Age
    Item 2, page 1; actual age in years.
  - 2. Income
    Item 7, page 2; range 1 (\$7,500 or less) to 6 (>\$50,000).
- B. Family background
  - 1. Family Strength
    Items 1,2, and 3, page 3; range 3 (no to all) to 6 (yes to all).
  - 2. Parental Strictness
    Item 4, page 3; range 1 (not at all strict) to 5 (extremely strict).
  - Physical Punishment
     Items 15a + 15b, page 6; range 2 (never to both questions) to 12 (over 20 times a month for each type of violence).
  - 4. Encouragement of Nonviolence
    Item 14, page 6; range 1 (never) to 6 (over 20 times per month).
  - 5. Self-Defense Training Item 16, page 7; range 1 (no) to 2 (yes).
- C. Psychosocial history
  - Sexual Abuse
    Section F, page 59, items a-h. No to all items = 1; Yes to items a,b, or c and no others = 2; yes to items d,e,or f and none higher = 3; yes to items q or h = 4.
  - 2. Delinquent Associations
    Items 5,6, & 7, pages 3-4; range 3 (no to all questions) to 9
    (extremely uncomfortable for fear friends would get in trouble with law).
  - 3. Suicide History Item 25, page 10; range 1 (no) to 2 (yes).
  - 4. Psychotherapy history Item 26, page 10; range 1 (no) to 2 (yes).
  - 5. Intoxicant Use

Items 9, 10, & II, pages 4-5; range 3 (do not drink) to 15 (drunk more than twice per week, typically drinking > 6 cans of beer or equivalent).

6. Sexual Values
Item 8, page 8; range 1 (approve intercourse under any circumstances) to 6 (do not approve of intercourse before marriage).

7. Number of Partners
Item 23, page 10; range 1 (none) to 9 (> 50 people).

8. Age at first intercourse Item 24b, page 10; actual age in years.

Sexual Orientation
 Item 22, page 9; range 1 (heterosexual) to 3 (homosexual).

### III. Assault Characteristics

#### A. Assault Context

1. Relationship Type
Item 2, page 41; range 1 (stranger) to 6 (relative).

2. Degree of Acquaintance
Item 3, page 41; range 1 (didn't know at all) to 5 (extremely well acquainted).

Prior Intimacy
 Item 13, page 44; range 1 (none at all) to 6 (sexual intercourse).

4. Age at Assault Item 5, page 42; actual age in years.

5. Alcohol/Drugs Involved
Items 9,10, pages 42-43; range 2 (neither man or woman using alcohol/drugs) to 6 (both parties using alcohol and drugs).

6. Prior Intercourse Item 14, page 44; range 1 (no) to 2 (yes).

#### B. Location

Social Context
 Item 12, page 43; range 1 (none) to 4 (spontaneous date).

2. Turf
Item 7, page 42; range 1 (his home) to 4 (her home).

Campus Location
 Item 8, page 42; range 1 (on campus) to 2 (off campus).

## C. Assault Severity

1. Number of Perpetrators
Item 1, page 41; range 1 (one man) to 3 (three or more men).

Number of Assaults by this Man
 Item 4, page 41, range 1 (1 time) to 5 (5 or more times).

Types of Force Item 11, page 43; no to all items a-e = 1, yes to a = 2, yes to b or c = 3, and yes to d or e = 5.

4. Perceived Yiolence
Item 23a, page 47; range 1 (not at all) to 5 (very much).

5. Negative Emotions
Items 24a-c, page 47; range 3 (not at all) to 15 (very much).

PAGE 27

#### D. Resistance

1. Clarity of Nonconsent Item 23b, page 47; range 1 (not at all) to 5 (very much).

Types of Resistance
Item 15a-f, page 44; no to all items a-f = 1, yes to a,b, or c (cognitive strategies) = 2, yes to d or e (escape strategies) = 3, and yes to f (physical resistance) = 4.

Degree of resistance
 Item 23d, page 47; range 1 (none) to 5 (very much).

4. Impact of resistance
Item 16, page 44; range 1 (he stopped) to 4 (he became even more aggressive).

5. Self-Defense Training Item 17a, page 44; range 1 (no) to 2 (yes).

Woman's Responsibility
 Item 23c, page 47; range 1 (not at all) to 5 (very much).

7. Man's Responsibility
Item 23e, page 47; range 1 (not at all) to 5 (very much).

#### IV. Post-Assault Characteristics

## A. Psychological Symptoms

1. Beck Depression Inventory
Items A - U, pages 52-26; range 1 (no depression) to 30
(severe depression). Scores of 16 and above suggest moderate to severe clinical depression.

2. State-Trait Anxeity Scale
Items 1-13, page 57. Item choices range from 1 (almost never) to 4 (almost always) and contains 7 reversed items; scale scores range from 20-80. Scores of 38.3 are the female undergraduate mean whereas scores of 46.6 are the psychiatric patient mean.

Quality of Relationships
 Item 17 a-d, page 7; range 1 (not at all) to 5 (very much).

4. Sexual Satisfaction: Affectional Item 21 a & b, page 9; range 2 (don't do it) to 10 (very satisfying).

5. Sexual Satisfaction: Intercourse Item 21 c, page 9; range 1 (don't do it) to 5 (very satisfying).

6. Number of Partners After
Item 25, page 48; range 1 (none) to 9 (> 50 people).

Changes in Feelings
 Item 34, page 51; range 1 (no) to 2 (yes).

## B. Yictim Conceptualization

Label for the Experience
 Item 35, page 51; range 1 (I don't feel I was victimized)
 to 4 (I believe I was a victim of rape).

Liklihood of Repetition
 Item 26 a + b, page 48; range 2 (no to both) to 4 (yes to both).

## C. Coincident Stressors

- . Time Since Assault
  Item 6, page 42; range 1 (< 3 months) to 6 (over 5 years).
- 2. Other Stressors Since
  Items 31 + 32 a-c, page 50; range 4 (no stressors) to 8
  (illness, death, and breakup since assault).

## D. Use of Services

- 1. Psychotherapy Postassault Item 29, page 49; range 1 (no) to 2 (yes).
- Used Crisis Services
   Item 20 + 22, pages 45-46; range 2 (no services) to 4 (emergency and campus services used).
- 3. Reported to Police Item 21, page 45; range 1 (no) to 2 (yes).
- Self-Defense Since Item 17b, page 44; range 1 (no) to 2 (yes).

#### E. Social Support

- 1. Told No One Item 18, page 45; range 1 (no) to 2 (yes).
- 2. Supportive Reactions
  Items 19a, 20a, 21a, 22a, pages 45-46; range 3 (not at all supportive) to 15 (very much supportive).

## Y. Psychological Characteristics

#### A. Rape Supportive Beliefs

Items 1-36, pages 66-68. Items scored 1(strongly disagree) to 5 (strongly agree). Possible range 36-180.

#### B. Positively Yalued Femininity

Items 1-40, pages 69-70. Femininity score from the Extended Personal Attributes Scale. Items scored 1 (not at all like me) to 5 (very much like me). Items are scored 0-4. Possible range 0-32. College female mean is 24.54.

#### C. Androgeny

Items 1-40, pages 60-70. Angrogeny score from the Extended Personal Attributes Scale. Items scored 1 (not at all like me) to 5 (very much like me). Items are scored 0-4. Possible range 0-32. College male mean is 16.61, college female mean is 13.22.

#### TABLE 7

## DESCRIPTIVE YARIABLES: MEN

#### I. Aggression Groups

A. Nonsexually Aggressive

No to all items 1-10 in Section C, pages 11-20.

B. Sexual Contact

Yes to items 1, 2, or 3; no to all other items in Section C, pages 11-20.

C. Sexual Coercion

Yes to items 6 or 7; no to all other items except 1,2, or 3 in Section C, pages 11-20.

D. Attempted Rape

Yes to items 4 or 5; no to all other items except 1,2,3, 6, or 7 in Section C, pages 11-20.

E. Rape

Yes to items 8, 9, or 10 in Section C, pages 11-20.

#### II. Pre-Assault Characteristics

#### A. Demographics

1. Age

Item 2, page 1; actual age in years.

2. Income

Item 7, page 2; range 1 (\$7,500 or less) to 6 (>\$50,000).

## B. Family background

1. Family Strength

Items 1,2, and 3, page 3; range 3 (no to all) to 6 (yes to all).

2. Parental Strictness

Item 4, page 3; range 1 (not at all strict) to 5 (extremely strict).

3. Modeling of Aggression

Items 15a + 15b, page 6; range 2 (never to both questions) to 12 (over 20 times a month for each type of violence).

4. Encouragement of Nonviolence

Item 14, page 6; range 1 (never) to 6 (over 20 times per month).

5. Self-Defense Training

Item 16, page 7; range 1 (no) to 2 (yes).

#### C. Psychosocial history

1. Sexual Abuse

Section F, page 59, items a-h. No to all items = 1; Yes to items a,b, or c and no others = 2; yes to items d,e,or f = and none higher = 3; yes to items q or f = and none higher = 3; yes to items q or f = and

2. Delinquent Associations

Items 5,6, & 7, pages 3-4; range 3 (no to all questions) to 9 (extremely uncomfortable for fear friends would get in trouble with law).

3. Suicide History

Item 25, page 10; range 1 (no) to 2 (yes).

4. Psychotherapy History

Item 26, page 10; range 1 (no) to 2 (yes).

5. Alcohol and Drug Use

Items 9, 10, & II, pages 4-5; range 3 (do not drink) to 15 (drunk more than twice per week, typically drinking > 6 cans of beer or equivalent).

6. Sexual Values

Item 8,- page 8; range 1 (approve intercourse under any circumstances) to 6 (do not approve of intercourse before marriage).

7. Number of Partners

Item 23, page 10; range I (none) to 9 (> 50 people).

8. Age at First Intercourse

Item 24b, page 10; actual age in years.

9. Sexual Orientation

Item 22, page 9; range 1 (heterosexual) to 3 (homosexual).

10. Discuss Women as Sex Objects
Item 8, page 4; range 1 (never) to 5 (daily).

11. Read Pornography

Item 12, page 5; range 1 (never) to 4 (very frequently).

#### III. Assault Characteristics

#### A. Assault Context

1. Relationship Type

Item 2, page 21; range 1 (stranger) to 6 (relative).

2. Degree of Acquaintance
Item 3, page 21; range 1 (didn't know at all) to 5
(extremely well acquainted).

Prior Intimacy

Item 13, page 24; range I (none at all) to 6 (sexual intercourse).

4. Age at Attack

Item 5, page 22; actual age in years.

5. Alcohol/Drugs Involved
Items 9, 10, pages 22-23; range 2 (neither man or woman using alcohol/drugs) to 6 (both parties using alcohol and drugs).

6. Prior Intercourse
Item 14, page 24; range 1 (no) to 2 (yes).

#### B. Location

1. Social Context

Item 12, page 23; range I (none) to 4 (spontaneous date).

Turf

Item 7, page 22; range 1 (his home) to 4 (her home).

3. Campus Location

Item 8, page 22; range 1 (on campus) to 2 (off campus).

#### C. Assault Severity

1. Number of Perpetrators

Item 1, page 21; range 1 (one man) to 3 (three or more men).

Number of Assaults by this Offender

Item 4, page 21, range 1 (1 time) to 5 (5 or more times).

3. Types of Force

Item 11, page 23; no to all items a-e=1, yes to a=2, yes to b or c=3, and yes to d or e=5.

- 4. Perceived Violence
  Item 23a, page 26; range 1 (not at all) to 5 (very much).
- Negative Emotions
   Items 24a-c, page 26; range 3 (not st all) to 15 (very much).
- 6. Positive Emotions
  Item 23e, page 26; range 1 (not at all) to 5 (very much).

#### D. Resistance

- 1. Perceived Monconsent
  Item 22b, page 26; range 1 (not at all) to 5 (very much).
- 2. Types of Resistance
  Item 15a-f, page 24; no to all items a-f = 1, yes to a,b,
  or c (cognitive strategies) = 2, yes to dor e (escape
  strategies) = 3, and yes to f (physical resistance) = 4.
- Degree of resistance
   Item 22d, page 26; range 1 (none) to 5 (very much).
- 4. Impact of resistance
  Item 16, page 24; range 1 (he stopped) to 4 (he became even more aggressive).
- 5. Woman's Responsibility
  Item 22c, page 26; range 1 (not at all) to 5 (very much).
- 6. Man's Responsibility
  Item 22e, page 26; range 1 (not at all) to 5 (very much).

#### E. Reactions to Assault

- 1. Reported to Police
  Item 17, page 24; range 1 (no) to 2 (yes).
- 2. Told Anyone Item 18, page 25; range 1 (no) to 2 (yes).
- 3. Rape Supportive Reactions
  Items 19a, 20a, 21a, pages 25-26; range 3 (reacted negatively) to 15
  (reacted positively).
- 4. Label for the Experience
  Item 26, page 27; range 1 (It was definitely not rape) to 4 (It definitely was rape).
- 5. Liklihood of Repetition
  Item 25 b, page 27; range 1 (no ) to 2 (yes).
- 6. Number of Partners After
  Item 24, page 27; range 1 (none) to 9 (> 50 people).

#### IY. Psychological Characteristics

#### A. Rape Supportive Beliefs

Items 1-36, pages 66-68. Items scored 1(strongly disagree) to 5 (strongly agree). Possible range 36-180.

#### B. Masculinity

Items 1-40, pages 69-70. Masculinity score from the Extended Personal Attributes Scale. Items scored 1 (not at all like me) to 5 (very much like me). Possible rangeis 0-32. Male college student mean is 22.31.

C. Androgeny

Items 10-40, pages 69-70. Androgeny score from the Extended Personal Attributes Scale. Item choices 1 (not at all like me) to 5 (very much like me). Items scored 0-4. Possible range-0-32. Male college student mean is 16.61.

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 9. (Methods)

The full sets of <u>dependent</u> variables that were derived from the questionnaire are listed in in the lower sections of Table 6 (Women) and Table 7 (Men). These full sets of variables were used to obtain descriptive data only. Later, it will be demonstrated that most of the variables resulted in significant differences between groups. Yet, due to the extremely large sample size, the magnitude of the differences was often not of practical significance.

Therefore, inferential analyses were based on reduced sets of variables that were constructed by a combination of rational and empirical procedures. First, the full sets of dependent variables were intercorrelated separately for each sex. The intercorrelations of dependent variables are found in Table 8 (Women) and Table 9 (Men). Because some subjects had not had any experience with sexual aggression/victimization, they did not complete the situational items. The intercorrelations of variables pertaining to early life experience, psychological, and current behaviors could be examined however. These correlations are found in Table 10 (Women) and Table 11 (Men). Items that failed to demonstrate meaningful differences between groups were eliminated. Then, the correlation matrices were used to identify homogeneous subsets of variables that were highly intercorrelated. Yariables that were found to be of similar content and to be highly intercorrelated were aggregated to produce a reduced number of variables. Standardized scales were not tampered with as this would obviate the advantages of an objectively scored and normed instrument. Through these procedures, a small number of variables each with a relatively large variance range resulted. Specifically, 13 variables resulted from reduction of the women's data and 11 variables resulted from the reduction of the men's data.

These reduced variables have been arranged into sets according the the point in time to which they refer and each set of variables has been given a rationally determined name. The reduced variables are listed in Table 12 (Women) and Table 13 (Men). For example, the male variables have been arranged into four sets. The first set, named <u>early experiences</u>, refers to historical information about the subject's background. The second set, named <u>psychological characteristics</u>, refer to measures of psychological adjustment and beliefs. These characteristics are assumed to have been influenced by the subject's early experiences and to have developed in the years that have intervened between early experiences and the present. The third set, named <u>current behavior</u>, is a current time measure reflecting the subject's behaviors and practices at the time the questions were answered. These behaviors are assumed to be influenced by all the earlier sets of variables. Finally, the fourth set, named <u>assault characteristics</u>, is also a current time measure and is assumed to be influenced by all the preceeding sets of variables.

Although the number of persons who refused to answer the questionnaire at all was small, many subjects took advantage of their right to refuse to answer any questions if they chose to skip them. Therefore, the problem with missing data had to be addressed in the scoring procedures. If the amount of data missing on a variable did not exceed 20% of the total sample, the group mean was substituted. When the individual was a member of the nonvictimized or nonsexually aggressive group, the mean of the of that group was used. When the individual was sexually aggressive or victimized to some degree, the offender mean or the victim mean was used. Items on standard scales were replaced by the appropriate mean only if the percentage of missing data was minimal. For example, persons who left more than 7 items blank on a 40

(Methods)

item scale were eliminated from data analysis. Persons who skipped 6 or fewer items were used in analyses with their missing data replaced by the appropriate group mean.

#### Data Analysis

The project had four specific aims including (1) determining incidence and prevalence rates for sexual aggression among college students (2) developing a descriptive data base on sexual aggression among college students (3) examining whether sexually aggressive men and sexually victimized women could be differentiated from comparison samples of nonsexually aggressive men and nonsexually victimized women, and (4) describing the traumatic impact of sexual aggression among college students.

The first aim was addressed through calculation of frequencies of subjects who responded to individual items of the Sexual Experiences Survey. Then, the proportion of subjects who class of sexual aggression/victimization was determined using both weighted and unweighted data. Finally, the relationships between prevalence and the control variables used to develop the sample and the demographic characteristics of the subject sample was examined through chi-square analysis.

The second aim was addressed through the use of descriptive statistical procedures (ANOVA and chi-square as appropriate) on the full set of dependent variables.

The third aim was addressed through the use of MANOVA/MANCOVA on the reduced sets of variables with planned comparisons between sexually nonaggressive/victimized subjects with each of the other groups. The analyses were accomplished by entering variables in stages with those that operate earliest in time entering first. With men, for example, in the first step the early experience variables were subjected to MANOYA (2 background variables by 5 levels of sexual aggression). Then, the ability of the early experience variables to predict psychological characteristics was examined. Those variables that significantly predicted psychological characteristics were used as covariates in step two. Therefore, in the second step, the psychopathology variables were subjected to MANCOYA, using early background variables as covariates. In the third step, current behaviors were subjected to MANCOYA using background variables and psychological characteristics as covariates. It his procedure was carried out until all sets of variables had been entered. The sexually nonaggressive and sexually nonvictimized comparison samples were substantially larger than the aggressive and victimized groups. Therefore, the comparison samples were weighted to approximate equal N's. For example, the sexually nonvictimized comparison sample actually contained 46% of the total number of women in the sample. Thowever, in the analyses the sexually nonvictimized sample was weighted to be equivalent to 20% of the total sample. Because of the large sample size and number of comparisons, this analysis plan was chosen because it is powerful yet conservative. The analysis allows the role of each set of variables to be examined with the effect of earlier variables controlled. In addition, the analysis adjusts the means for the nonindependence of multiple comparisons.

The fourth aim was addressed through the use of hierarchial multiple regression. Using the measures of psychological impact as the independent variables, the reduced sets of variables were entered in steps. Those variables that operate earliest in time were entered first. For depression, for example, in the first step the early experience variables were entered into a Item No.

9. (Methods)

stepwise multiple regression. Those variables that significantly predicted depression were retained. In the second step, the significant background variables were entered first and then the psychological characteristics were stepped in. Those psychological characteristics that significantly predicted depression were retained. In the third step, significant background and psychological variables were entered and then the current behavior variables were stepped in. This procedure was continued until all the sets of reduced variables had been entered.

12. (Results)

#### RESULTS

The data analyses addressed four questions:

- (1) the incidence and prevalence of sexual aggression and victimization among college students,
- (2) the descriptive characteristics of the assaults reported by college students, the early experiences and psychological characteristics of sexually aggressive men and sexually victimized women, and the traumatic impact of rape
- (3) the differentiation of sexually victimized women from nonvictimized women and sexually aggressive men from nonsexually aggressive men in terms of early experiences, psychological characteristics, and current behavior, and
  - (4) prediction of the emotional impact of rape.

The results that are relevant to each question are presented in the following sections.

#### Incidence and Prevalence of Sexual Aggression/Yictimization

#### Prevalence by Individual Acts of Sexual Aggression/Yictimization

The unweighted frequencies of response for each item of the Sexual Experiences Survey (Koss & Oros, 1982; Koss & Gidycz, 1985; see section C of questionnaire) are presented in Table 14. The frequency of the various forms of victimization ranged from 44% of women who report having experienced unwanted oral or anal penetration by force. Respondents indicated that they have had multiple exposures to each experience. Women who had indicated unwanted, forced intercourse reported that this type of victimization had occurred a mean of 2.2 times to them. The frequency with which men reported various forms of sexual aggression ranged from 19% of men who said that they had obtained sexual contact through the use of coercion to 1% of men who indicated that they had obtained oral or anal penetration through the use of force. Male respondents revealed that they had engaged in each act on multiple occasions. For example, those men who had obtained sexual intercourse through force had done so a mean of 2.3 times.

#### Prevalence by Categories of Sexual Aggression/Victimization

Prevalence figures for individual acts are difficult to interpret since individuals may have had multiple experiences. Thus, the total number of persons who report experiences with the individual acts of sexual aggression totals more than 100% of the population. To determine the proportion of individuals who have engaged in/experienced some form of sexual aggression, respondents were categorized according to the highest degree of sexual victimization/aggression they reported. (The rules on which these caregories were based are found in Tables 6 and 7). Using weighted data to correct for regional disproportions, 45.6% of women respondents revealed no experiences whatsoever with sexual victimization whereas 14.5% reported unwanted sexual contact, 11.2% reported sexual coercion, 11.8% reported attempted rape, and 15.3% had been raped. These data are presented in Table 15. Examination of weighted male data indicates that 74.8% of men reported that they had engaged in no forms of sexual aggression whereas 9.8% acknowledge using force or coercion to obtain sexual contact, 6.9% admit to acts of sexual coercion, 3.2% report attempts to rape, and 4.6% report behavior that meets legal definitions of rape. Comparison of weighted and nonweighted data indicate that the differences are small and

that the effect of weighting is to render the estimates very slightly more conservative.

#### Relationship of Sexual Aggression/Victimization to Control Variables

The relationship of prevalence rates to the levels of sexual victimization and the control variables used to design the sample was examined. No significant differences in the prevalence of sexual victimization were found according to the size of the city where the institution of higher education was located ( $X^2 = 5.55$ , p = .697), the size of the institution ( $X^2 = 6.35$ , p = .608), the type of institution ( $X^2 = 10.37$ , p = .240), or whether the minority enrollment of the institution was above or below the national mean ( $X^2 = 4.03$ , p = .401). However, rates of sexual victimization did vary by region ( $X^2 = 63.00$ , p = .001) and by the governance of the institution ( $X^2 = 22.93$ , p = .003). The rate of rape was twice as high in private colleges (14%) and major universities (17%) as it was at religiously affiliated institutions (7%). Reported victimization rates were slightly higher in the Great Lakes and Plains States than in other regions. These data are summarized in Table 16.

The relationships between prevalence rates of sexual aggression and the control variables were nonsignificant for city size ( $X^2$ =6.41, p=.600), institution size ( $X^2$ =3.76, p=.878), minority enrollment ( $X^2$ =4.84, p=.303), governance ( $X^2$ =13.66, p=.091), and type of institution ( $X^2$ =3.99, p=.858). The only control variable that was related to reported rates of sexual aggression was region of the country ( $X^2$ =56.25, p=.001). The rate at which men admitted rape was twice as high in the Southeast (6%) as the rate in the Plains States (3%) and three times as high as the rate in the West (2%). These data are presented in Table 17.

#### Relationship of Sexual Aggression/Victimization to Demographic Variables ...

The relationships between the prevalence rates for sexual victimization and subject demographic variables was also studied including income, religion, and ethnicity. Among women, no significant differences were found for income (F= .31, p= .871) and religion ( $X^2$  = 17.86, p= .332). Differences were found, however, in the rates at which various types of victimization were reported by ethnic groups ( $X^2$  = 37.05, p= .002). For example, the prevalence of rape was 16% among White women, 10% among Black women, 12% among Hispanic women, 7% among Asian women, and 40% among Native American women. The prevalence rates for sexual victimization by ethnic group are presented in Table 18.

No significant differences were found between the prevalence rates for sexual aggression and male demographic variables including religion ( $X^2 = 20.98$ , g = .179) and income (F = .08, p = .987). The rates at which various types of sexual aggression were reported differed by ethnic group however ( $X^2 = 55.55$ , g = .000). For example, the prevalence at which rape was reported by men was 4% among White men, 10% among Black men, 7% among Hispanic men, 2% among Asian men, and 0% among Native American men. The prevalence rates for sexual aggression by ethnic group are presented in Table 19.

#### Incidence of Sexual Aggression/Victimization

Respondents were asked to indicated how many times during the previous one year they had engaged in/experienced each item in the Sexual Experiences Survey (See questionnaire, section C). These responses were used to calculate one year/incidence rates for each item. These data are reported in Table 20. If the incidence figures are condensed into levels of sexual victimization they reveal that in a one year period on 33 campuses, 3,187 women experienced 328 rapes, they reveal that in a one year period on 33 compuses, 3,101 women are so unwanted sexual 543 attempted rapes, 837 episodes of sexual coercion, and 2,024 experiences of unwanted sexual fields attempted rapes, 837 episodes of sexual coercion, and 2,024 experiences of unwanted sexual fields. contact. These data are found in Table 21. Dividing these incidents by the number of women in the population gives the following rates per 1.000 college women per uear: rape 103/1.000: attempted rape 170/1,000; sexual coercion 263/1,000; and sexual contact 635/1,000. The individual rates were then combined to determine the rate of criminal sexual victimization (rape, attempted rape, and forceful sexual contact) in this population which was 336 per 1,000 college women in a one year period.

Using male responses to the Sexual Experiences Survey, 187 rapes, 157 attempted rapes, 854 episodes of unwanted sexual contact, and 327 situations of sexual coercion occurred in a one year period. Dividing these incidents by the number of men in the population gives the following rates per 1,000 college men per year: rape 63/1,000; attempted rape, 53/1,000, sexual coercion 110/1,000; and sexual contact 287/1,000. The individual rates were then combined to determine the rate of criminal sexual conduct by men (rape, attempted rape, forceful sexual contact) in this population which is 138 per 1,000 men for a one year period. These data are presented in Table 21.

#### Sexual Aggression/Yictimization: Descriptive Characteristics

A second goal of the project was to develop a descriptive picture of the sexual aggression/victimization experiences that are reported by college students, of the early experiences, psychological characteristics, and current behavior of students, and of the traumatic impact of sexual victimization. In the following sections, simple descriptive statistics will be reported to accomplish this goal. It must be noted that due to the large sample size, differences that have no real practical significance can reach statistical significance. In addition, whenever a large number of comparisons are made, the risk increases that some statistically significant differences actually arose by chance. Therefore, the following analyses are presented for descriptive purposes only. For inferential analyses, the large number of variables was reduced. appropriate adjustments in means were made for multiple nonindependent comparisons, and only planned comparisons were made. These analyses are presented later.

#### Yictimizations Reported by Women

The items in section D of the questionnaire request detailed information about the most serious victimization that a woman has experienced since the age of 14. These dependent variables were analyzed by chi-square analysis for dicotomous data and ANOVA for continuous data using the sexual victimization groups as independent variables. The results of the ANOYAs are reported in Table 22 and the results of the Chi-square analyses are reported in Table 23. These analyses demonstrate that rape victims describe their victimizations differently than women who have experienced lesser degrees of sexual victimization.

12. (Results)

Using the data in Tables 22 and 23, the following "portrait" can be drawn of the rapes experienced by college women. The rapes happened 1-2 years ago when the victim was 18-19 years old ( $\underline{M}$  age = 18.51), and 95% involved one offender. Only 12% of the offenders were strangers while 84% were some type of acquaintance including 57% who were "dates." On average, prior mutual intimacy had occurred with the offender to the level of petting above the waist ( $\underline{M}$  = 3.52). Nevertheless, victims believed that they had made their nonconsent to have sexual intercourse "quite" clear ( $\underline{M}$ = 4.05).

The rapes happened primarily off campus (86%), equally as often in the man's house or car as in the woman's house or car. Nearly three-quarters of offenders (73%) were thought to be drinking or using drugs while the victim admitted using intoxicants in 55% of the situations. Typically, the amount of force used by the offender was moderate ( $\underline{M} = 3.88$ ) and involved twisting the victim's arm or holding her down. Only 9% of the rapes involved hitting or beating and only 5% involved weapons. The victims rated their amount of resistance as moderate ( $\underline{M} = 3.80$ ). Various forms of resistance were used by most women including reasoning (84%) and physically struggling (70%). Many women had been virgins at the time of their rape (41%). During the rape, victims felt quite scared ( $\underline{M} = 3.66$ ), angry ( $\underline{M} = 3.97$ ), and depressed ( $\underline{M} = 3.93$ ). Victims also felt "somewhat" responsible for what had happened ( $\underline{M} = 2.80$ ) but believed that the men were much more responsible ( $\underline{M} = 4.29$ ).

After the rape, only 5% of victims reported to police and just 5% visited a crisis center. Those who reported to police rated the reaction they received as "not at all supportive" (M=1.02) On the other hand, family (M=3.70) and campus agency reaction (M=4.00) were seen as supportive. Almost half of rape victims (42%) told no one at all about their assault. Surprisingly, 42% of the women indicated that they had had sex again with the offender on a later occasion but it is not known if this was forced or voluntary. Most relationships did break up subsequent to the rape (87%). Only 27% of the women whose experience met legal definitions of rape labeled themselves as rape victims. Most women were more likely to see there experience as "a serious miscommunication" or "a crime other than rape." Many women (41%) expect a similar experience to happen again in the future.

#### Assaults Reported by Men

The items in Section D of the questionnaire request detailed information about the most serious sexual assault that a man has engaged in since the age of i.4. These dependent variables were analyzed by chi-square analysis for dicotomous data and ANOVA for continuous data using the sexual aggression groups as independent variables. The results of the ANOVAs are reported in Table 24 and the results of the Chi-square analyses are reported in Table 25. These analyses demonstrate that men who report behavior that meets legal definitions of rape describe the episode differently than men who report lesser degrees of sexual aggression.

Using the information contained in these two tables, the following "portrait" can be drawn of the rapes perpetrated by college men. The rapes reported by college me happened 1-2 years ago when the man was 18-19 years old ( $\underline{M}=18.49$ ) and 84% involved or offender. Only 15% of the victims were strangers while 85% were some kind of acquaintance including 61% who were "dates." On average, men reported consentual intimacy with the victim to the level of petting below the waist before the rape occurred ( $\underline{M}=4.37$ ). Men felt that the woman had failed to make it clear that she did not want intercourse ( $\underline{M}=1.80$ ). Furthermore, men indicated that

they had done the behavior that they describe, which is here labeled rape, a mean of 2.29 times to the woman.

Most of the rapes reported by men happened off campus (86%). Nearly three-quarters of the men (74%) admitted to the use of intoxicants before the rape took place and they stated that three-quarters of the women were using intoxicants also. Typically, the man perceived his amount of force as mild ( $\underline{M}=2.85$ ). Only 3% of perpetrators admitted hitting or beating the victim and only 4% stated that they used a weapon. Men perceived the woman's resistance as minimal ( $\underline{M}=1.83$ ). Nevertheless, 36% of the offenders noted that the victim tried to reason with them and 12% observed that she physically struggled. Men noted that the resistance had no effect on them ( $\underline{M}=2.59$ ). Few men were virgins at the time the rape took place (12%). Men stated that they experienced minimal fear, anger, or depression at the time of the assault but they did experience some pride ( $\underline{M}=2.59$ ). Men felt that the woman was more responsible for what happened ( $\underline{M}=2.85$ ) than they were ( $\underline{M}=2.43$ ).

To the man's knowledge, only 2% of the rapes were ever reported to the police. Many men report that they had sex again with the same women after the incident occurred (55%) and expect a similar incident to occur again in the future (47%). Only a single man saw his behavior as rape while 84% of the men described their behavior as "definitely not a rape!" In the time since the assault, the men report having had sexual intercourse with approximately 2-5 women.

Background, Psychological Characteristics and Current Behavior

The full set of background and psychological characteristics were analysed by chi-square analysis for dicotomous data and ANOYA for continuous data using sexual aggression/victimization groups as independent variables. The results of these analyses are presented in Tables 26, 27, 28, and 29. While these tables can be used to draw descriptive "portraits" of-college students, they will also be used to interpret the results of the planned comparisons that are presented later. The planned comparisons were based on a reduced set of variables. Tables 25, 26, 27, and 28 contain the individual variables that were combined to form the reduced set. Second, the planned comparisons were based on group means that were adjusted for the nonindependence of multiple comparisons. Therefore, the group differences on the adjusted means are smaller than on the raw means. To establish the clinical significance of a standardized test score, raw means are necessary. It can be seen from these tables that the groups of women and the groups of men differ significantly on most variables although the absolute size of the differences on many variables is small.

Using the data in Tables 26 and 27, the following descriptive portrait can be drawn of the background and psychological characteristics of the rape victim: Women who have been raped here somewhat more likely than nonvictimized women to have come from a home where the parents are divorced (31%), to have a step father (12%), and to have lived without their mother for a period of time (18%). The family background is described as "somewht srict" ( $\underline{M}$ = 3.21). On the average, aggression was discouraged; victims were punished 1-2 times per months for physical play, roughhousing, or wrestling with siblings and friends (( $\underline{M}$ = 1.82). Victims reported that they felt only "a little" uncomfortable with the high school friends they had from fear that they might get in trouble with the law ( $\underline{M}$  = 1.77). While just 12% of rape victims stated that they had ever run away from home, they were twice as likely to have run away than nonvictimized women. Yictims were 16 years old ( $\underline{M}$ = 16.32) when they first had sexual intercourse either

di ve ar per ar

5

Item No.

12. (Results)

forced or voluntarily. Almost half of rape victims have considered suicide at some time in their lives (43%) and have had psychotherapy (43%).

Currently, victims describe their intoxicant use as 1-3 times per month ( $\underline{M}$ = 3.19), usually no more than 4 cans of beer of 3 glasses of wine or 3 drinks of distilled spirits ( $\underline{M}$ = 2.55). They state that they get drunk less than once a month but at least once per year ( $\underline{M}$ = 2.09). Victims believe that sexual intercourse is appropriate if a couple is dating regularly ( $\underline{M}$ = 3.12) and 90% of them have had sexual intercourse (Note: "Sexual intercourse" in the Sexual Experiences Survey is defined as "penetration no matter how slight, ejaculation is not necessary." In normal usage, many women do not define an experience as sexual intercourse unless relations were completed.) Most victims have had sexual intercourse with 2-5 different people ( $\underline{M}$ = 2.73). Mean scores on the Femininity Scale ( $\underline{M}$ = 26.14) and Androgeny Scale ( $\underline{M}$ = 12.83) are close to college female means (Femininity = 24.54; Androgeny = 13.22).

The data in Tables 28 and 29 can be used to draw a descriptive portrait of the college men who report behavior that meets legal definitions of rape. These men are no more likely than other men to have divorced parents, to have a step father, or to have lived without their mother for a period of time. They describe their family background as quite strict ( $\underline{M}$ = 3.30). Physical aggression was punished once or twice per month (M= 2.49). Family violence in the forms of parents hitting the children ( $\underline{M} = 1.99$ ) or each other ( $\underline{M} = 1.42$ ) also occurred about 1-2 times per month. One sexually aggressive man in eight stated that he had run away from home at some point while growing up (12%). Nearly half have studied self-defense (44%) and all have had sexual intercourse (99%) which occurred for the first time at approximately 15 years old (M=15.34). These men approve sexual intercourse under any circumstances (M=1.88) and have had 2-5 different partners ( $\underline{M}$  = 2.73). Currently, they drink one to two times per week (M = 3.94), usually no more than 5 or 6 cans of beer or 4 glasses of wine or 4 grinks of distilled spirits (M= 3.69). They report becoming intoxicated 1-3 times per month (M = 2.75). When they are with friends, these men hear talk on a daily basis 'that speculates about "how a particular woman would be in bed" (11 = 4.25). At least one of the following magazines are read very frequently (M = 3.94): Playboy, Penthouse, Chic, Club, Forum, Gellery, Genesis, Oui, or Hustler. The men's mean score on the Masculinity Scale (M = 23.11) and Androgeny Scale (M = 23.11) 15.31) are close to the male college student means (Masculinity = 22.31; Androgeny = 16.61).

#### Post-Assault Impact of Sexual Victimization

The full set of postassault variables were analysed by chi-square analysis for dicotomous data and ANOVA for continuous data using sexual victimization groups as independent variables. The results of these analyses are presented in Tables 30 and 31. While these tables can be used to draw a descriptive portraits of the impact of sexual assault, they will also be used to interpret the results of the planned comparisons that are presented later.

Using the data presented in Tables 30 and 31, the following descriptive portrait can be drawn of the impact of rape on college women: Since the rape occurred, nearly one-third of victims have thought about suicide (29%). Of those who have thought about suicide, almost a half indicate that the victimization was the cause of the suicidal thoughts. Approximately one-third (31%) of the victims have sought psychotherapy since their rape and nearly two-thirds of them attribute the need for therapy directly to the rape. One rape victim in five took self-defense training as a response to the assault (22%). When victims were asked to compare their rape to

other major life traumas they have experienced such as relationship breakups, illness, and deaths; 64% rated the rape as traumatic as these other life events. Most rape victims (82%) believe that the experience has permanently changed their behavior and feelings. Currently, rape victims indicate that they are "somewhat" able to get close to others (M= 3.46), to trust others (M= 3.44), and to maintain relationships (M= 3.54). They find kissing or hugging very satisfying (M= 4.72), and sexual intercourse "somewhat" satisfying (M= 4.03). Scores on the Trait Anxeity Scale (M= 43.10) are above the college female mean (M= 38.30) but below the psychiatric population mean (M= 46.60). Scores on the Beck Depression Inventory (M= 8.05) are significantly below the cutoff for clinical depression (16).

## Differentiation of Sexual Aggression/Yictimization Groups

A third goal of the study was to attempt to differentiate sexually victimized women from nonvictimized women and sexually aggressive men from nonsexually aggressive men in terms of early experiences, psychological characteristics, and current behavior. This goal was addressed through the use of MANOYA/MANCOYA with planned comparisons between the sexual victimization/aggression groups and the nonsexually victimized/aggressive comparison samples.

#### Yictimized Yersus Nonvictimized Women

The adjusted means for the groups of women on the reduced sets of variables are found in Table 32. The results of planned comparisons of sexually victimized and nonsexually victimized women on early experiences are found in Table 33, the results of planned comparisons on psychological characteristics are found in Table 34, the results of planned comparisons on current behavior are found in Table 35, and the results of planned comparisons on assault characteristics are found in Table 36.

Rape Victims Vs. Nonvictims. Rape victims were significantly differentiated from nonvictimized women by early experience variables (Pillais approximate multivariate F=57.29, p=.000). Rape victims were significantly different from nonvictimized women on Family Stability (F=8.09, p=.004), Family Yiolence (F=30.28, p=.000), Early Sexual Experience and Abuse (F=268.83, p=.047). Controlling for early experiences, rape victims could be differentiated from nonvictimized women by psychological characteristics (Pillais approximate multivariate F=6.35, p=.000). The groups differed in Rape Supportive Beliefs (F=9.38, p=.002) and in Androgeny (F=6.34, p=.012). Whereas, on most variables the rape victims scored significantly higher than nonvictims, on Rape Supportive Beliefs they obtained a lower score. The groups did not differ in Femininity. With early experiences and psychological characteristics controlled, rape victims differed from nonvictimized women in current behavior (Pillais approximate multivariate F=31.48, p=.000). The groups differed in Alcohol/Drug Use (F=29.47, p=.000) and Sexual Behavior (F=37.19, p=.000).

Attempted Rape Victims Vs. Nonvictims. Attempted rape victims could be differentiated from nonsexually victimized women on early experience variables (Pillais Approximate F=11.11, g=.000). Attempted rape victims were significantly different on Family Ylolence (F=9.17, g=.002) and Early Sexual Abuse and Experiences (F=50.98, g=.000). They did not differ from sexually nonvictimized women on Family Stability, Suicide History, or Treatment History. Controlling for early experiences, attempted rape victims could not be differentiated from

12. (Results)

nonvictimized women by psychological characteristics (Pillais approximate multivariate F = 2.02, g = .109). With early experience controlled, attempted rape victims could be differentiated from nonsexually victimized women by current behavior variables (Pillais approximate multivariate F = 14.02, g = .000). The groups differed on Alcohol/Drug Use (F = 22.00, g = .000) and Sexual Behavior (F = 7.46, g = .006).

Sexual Coercion Victims Vs. Nonvictims. Victims of sexual coercion could be differentiated from sexually nonvictimized women on early experience variables (Pillais approximate F=20.81, p=.000). They differed on Family Violence (F=3.86, p=.050) and Early Sexual Abuse and Experiences (F=103.47, p=.000). They did not differ on Family Stability, Suicidal Thoughts or Treatment History. Controlling for early experiences, victims of sexual coercion could be differentiated from nonvictimized women on psychological characteristics (Pillais approximate multivariate F=4.58, p=.003). The groups differed in Rape Supportive Beliefs (F=4.67, p=.031) and Androgeny (F=5.13, p=.024). They did not differ in Femininity. With early experiences and psychological characteristics controlled, victims of sexual coercion could be differentiated from nonsexually victimized women on current behavior variables (Pillais approximate multivariate F=34.39, p=.000). The groups differed on Alcohol/Drug Use (F=26.39, p=.000) and Sexual Behavior (F=46.29, p=.000).

Sexual Contact Victims Vs. Nonvictims. Victims of sexual contact could be differentiated from sexually nonvictimized women by early experience variables (Pillais approximate F=7.32, = .000). They differed in Family Violence (F=4.33, p=.038), Early Sexual Abuse and Experiences (F=19.20, p=.207), and Treatment History (F=8.63, p=.003). They did not differ in Family Stability or Suicide History. Controlling for early experiences, victims of sexual contact could be differentiated from nonvictimized women on psychological characteristics (Pillais approximate multivariate F=4.89, p=.002). The groups differed in Androgeny (F=11.23, p=.001). They did not differ in Rape Supportive Beliefs or Femininity. With early experiences and psychological characteristics controlled, victims of sexual contact could be differentiated from nonsexually victimized women by current behavior variables (Pillais approximate multivariate F=5.91, p=.003). The groups differed on Alcohol/Drug Use (F=9.27, p=.002). They did not differ in sexual behavior.

Rape Victims Vs. Sexual Coercion Victims. Rape victims could be differentiated from victims of sexual coercion on early experience variables (Pillais approximate multivariate F=7.09, p=.000). They differed in Family Violence (F=9.43, p=.002), Suicide History (F=7.30, p=.007), and Early Sexual Abuse and Experience (F=25.56, p=.000). They did not differ in Family Stability or Treatment History. Controlling for early experiences, rape victims were not different from victims of sexual coercion on psychological characteristics. With early experiences controlled, rape victims could not be differentiated from victims of sexual coercion by current behavior variables (Pillais approximate multivariate F=.42, p=.655). With all earlier variables controlled, rape victims could be differentiated from victims of sexual coercion by assault characteristics (Pillais approximate multivariate F=116.32, p=.000). The assaults experienced by each group differed in Context (F=94.78, p=.000), in Severity (F=284.87, p=.000), and in postassault Support (F=28.91, p=.000).

Attempted Rape Victims Vs. Sexual Coercion Victims. Attempted rape victims could be differentiated from victims of sexual coercion on early experience variables (Pillais approximate multivariate F = 2.30, g = .043). They differed in Early Sexual Abuse and

GRANT NUMBER R01-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

(Results) Item No.

> Experiences (F = 8.90, g = .003). They did not differ in Family Stability, Family Yiolence, Suicide History or Treatment History. Controlling for early experience, attempted rape victims were not different from victims of sexual coercion on psychological variables. With early experiences controlled, victims of attempted rape could be differentiated from victims of sexual coercion on current behavior variables (Pillais approximate multivariate F = 9.45, p = .000). The groups differed on Sexual Behavior (F = 18.57, p = .000). They did not differ in Alcohol/Drug Use. With all earlier variables controlled, attempted rape victims could be differentiated from victims of sexual coercion by the characteristics of the assault they experienced (Pillais approximate Multivariate F = 31.74, p = .000). The assaults experienced by each group differed in Context (F = 89.92, g = .000), Severity (F = 16.71, g = .000), and in postassault Support (F = 28.91, p = .000).

> Sexual Contact Victims Versus Sexual Coercion Victims. Victims of sexual contact could be differentiated from victims of sexual coercion on early experience variables (Pillais approximate multivariate F = 10.67, g = .000). They differed in Early Sexual Abuse and Experiences (F = 37.01, p = .000), Suicide History (F = 5.96, p = .015), and Treatment History (F = 16.07, g = .000). They did not differ in Family Stability of Family Yiolence. Controlling for early experiences, victims of sexual contact could not be differentiated from victims of sexual coercion on psychological variables. With early experiences controlled, victims of sexual contact could be differentiated from victims of sexual coercion on current behavior variables (Pillais approximate multivariate F = 41.15, p = .000). The groups differed on Alcohol/Drug Use (F = 6.30, p= .012) and Sexual Behavior (F = 76.61, p= .000). With all earlier variables controlled, victims of sexual contact could be differentiated from victims of sexual coercion by assault characteristics (Pillais approximate Multivariate F = 21.09, p =.000). The assaults experienced by each group differed in Context (F = 60.54, p = .000). They did not differ in Severity or in postassault Support.

#### Sexually Aggressive Versus Sexually Nonaggressive Men

The adjusted means for the groups of men on the reduced sets of variables are found in Table 37. The results of planned comparisons of sexually aggressive and nonsexually aggressive men on early experiences are found in Table 38, the results of planned comparisons on psychological characteristics are found in Table 39, the results of planned comparisons on current behavior are found in Table 40, and the results of planned comparisons on assault characteristics are found in Table 41.

Rapists Vs. Sexually Nonaggressive Men. Rapists were significantly differentiated from sexually nonaggressive men by early experience variables (Pillais approximate multivariate F = 27.68, p = .000). The groups differed on early experience variables including Family Violence (F = 21.86, p = .000), and Early Sexual Experience and Abuse (F = 36.63, p = .000). Controlling for early experiences, rapists could be differentiated from sexually nonaggressive men by psychological characteristics (Pillais approximate Multivariate F = 5.21, p = .000). The groups differed in Rape Supportive Beliefs (F = 20.86, p = .000) and Hostility toward Women (F = 14.23, g = .000). They did not differ in MMPI Scale 4, Masculinity, or Androgeny. With early experiences and psychological characteristics controlled, rapists differed from sexually nonaggressive men in current behavior (Pillais approximate multivariate F = 25.47, p= .000). The groups differed in Releasers ( F = 37.88 p = .000) and Sexual Behavior (F = .000) and Sexual Behavior (F = .000). 14.65, p = .000).

## FINAL REPORT GUIDELINES CONTINUATION PAGE

12. (Results) Item No.

> Attempted Rapists Vs. Sexually Nonaggressive Men. Attempted rapists were significantly differentiated from sexually nonaggressive men by early experience variables (Pillais approximate multivariate F = 13.62, p = .000). The groups differed on early experience variables including Family Violence (F= 9.95, p = .002), and Early Sexual Experience and Abuse (F = 18.81, p = .000). Controlling for early experiences, rapists could be differentiated from sexually nonaggressive men by psychological characteristics (Pillais approximate Multivariate F = 4.43, p = .001). The groups differed in Rape Supportive Beliefs (F = 10.82, p = .001), Hostility toward Women (F = 18.18, p = .000), MMPI Scale 4 (F = 6.04, p = .014). They did not differ in Masculinity, or Androgeny. With early experiences and psychological characteristics controlled, attempted rapists differed from sexually nonaggressive men in current behavior (Pillais approximate multivariate F = 8.14, g = .000). The groups differed in Releasers (F = 15.14 p = .000) but not in Sexual Behavior.

> Sexually Coercive Men Ys. Sexually Nonaggressive Men. Sexually coercive men were significantly differentiated from sexually nonaggressive men (Pillais approximate multivariate F = 22.35, g = .000) on early experience variables. The groups differed on Early Sexual Experience and Abuse (F = 43.28, p = .000) but not on Family Violence. Controlling for early experiences, sexually coercive men could be differentiated from sexually nonaggressive men by psychological characteristics (Pillais approximate Multivariate F = 2.22, p = .050). The groups differed in Hostility to Women (F = 7.95, g = .000) and MMPI Scale 4 (F = 4.20, g = .041). They did not differ on Rape Supportive Beliefs, Masculinity, or Androgeny. With early experiences and psychological characteristics controlled, sexually coercive men differed from sexually nonaggressive men in current behavior (Pillais approximate multivariate F = 18.84, p = .000). The groups differed in Releasers ( F = 12.26 p = .000) and Sexual Behavior (F = 12.26 p = .000) and Sexual Behavior (F = 12.26 p = .000) 26.64, p = .000).

> Sexual Contact Vs. Sexually Nonaggressive Men. Men who had obtained sexual contact exploitatively could be significantly differentiated from nonsexually aggressive men on early experience variables (Pillais approximate multivariate F = 4.96, p = .007). The groups differed on early experience variables including Family Yiolence (F = 6.20, p = .013), and Early Sexual Experience and Abuse (F = 4.30, p = .038). Controlling for early experiences, sexual contact could be differentiated from nonaggression by psychological characteristics (Pillais approximate Multivariate F = 3.02, p = .011). The groups differed in MMPI Scale 4 (F. = 4.53, p = .034) and Hostility toward Women (F = 13.21, p = .000). They did not differ in Rape Supportive Beliefs, Masculinity, or Androgeny. With early experiences and psychological characteristics controlled, sexual contact differed from nonaggression in current behavior (Pillais approximate multivariate F = 4.64, p = .010). The groups differed in Releasers (F = .010).  $4.54 \, \mathrm{g} = .001$ ) and Sexual Behavior (F = 5.05,  $\mathrm{g} = .025$ ).

> Rapists Ys. Sexually Coercive Men. Rapists were significantly differentiated from sexually coercive men on early experience variables (Pillais approximate multivariate F = 4.60, p = .010). The groups differed on Family Yiolence (F = 9.22, p = .002) but not on Early Sexual Experience and Abuse. Controlling for early experiences, rapists could be differentiated from

12. (Results)

sexually coercive men by psychological characteristics (Pillais approximate Multivariate F = 3.02, p = .011). The groups differed in Rape Supportive Beliefs (F = 14.80, p = .000). They did not differ in MMPI Scale 4. Hostility toward Women, Masculinity, or Androgeny. With early experiences and psychological characteristics controlled, rapists differed from sexually coercive men in current behavior (Pillais approximate multivariate F = 5.49, p = .004). The groups differed in Releasers (F = 10.70 g = .001) but not in Sexual Behavior. With all earlier variables controlled, rapists could be differentiated from sexually coercive men by assault characteristics (Pillais approximate Multivariate F = 5.43, p = .005). The assaults by each group of men differed in Context (F = 5.87, p = .016) and in the Severity (F = 4.05, p = .045).

Attempted Rapists Vs. Sexually Coercive Men. Attempted rapists could not be differentiated from sexually coercive men by early experiences (Pillais approximate multivariate F = 2.01, p = .135). The groups also did not differ in psychological characteristics (Pillais approximate Multivariate F = 2.00, p = .078). The groups did differ in current behavior however (Pillais approximate multivariate F = 5.28, p = .005). The groups differed in Sexual Behavior ( F =9.29 p = .002) but not in releasers. With all earlier variables controlled, attempted rapists could be differentiated from sexually coercive men by assault characteristics (Pillais approximate Multivariate F = 6.13, g = .002). The assaults by each group of men differed in Context (F = 12.29, p = .000) but not in Severity.

Sexual Contact Vs. Sexually Coercive Men. Sexual Contact could be significantly differentiated from sexual coercion on the basis of early experiences (Pillais approximate multivariate F = 12.72, p = .000). The groups differed on Early Sexual Experience and Abuse (F = 24.51, p = .000). .000). They did not differ on Family Yiolence. Controlling for early experiences, sexual contact could not be differentiated from sexual coercion by psychological characteristics. With early experiences controlled, sexual contact differed from sexual coercion in current behavior (Pillais approximate multivariate F = 9.73, p = .000). The groups differed in Releasers ( F = 3.96 p = .000). .000) and Sexual Behavior (F = 15.09, p = .000). With all earlier variables controlled, men who obtained sexual contact exploitatively could be differentiated from sexually coercive men by assault characteristics (Pillais approximate Multivariate F = 5.79, p = .003). The assaults by each group of men differed in Context (F = 4.03, p = .045) and in the Severity (F = 8.52, p = .045).004).

### Sexual Victimization: Predicting its Impact

The sets of early experience, psychological, current behavior, and assault variables were also used as predictors to study the impact of sexual victimization as reflected by the victim's label for her experience, the Beck Depression Inventory score, and the State-Trait Anxiety score. In the analyses, hierarchial multiple regression was used. Yariables were ordered in time and entered in steps. Those that significantly predicted the criterion were entered on the subsequent step before the next set of variables was stepped in. Thus, it was possible to examine the incremental contribution of each set of variables with the effects of earlier variables controlled.

The item that asked victims about their label for the assault was a continuous item. Therefore, it was possible to use multiple regression to predict it. This analysis was confined to the 477 rape victims (of whom 27% considered their experience definitely rape, 16% who

	GRANT	NUMBER	
֡		1 - MH - 3	161

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

12. (Results)

thought it was a crime but not rape, 28% who thought it was a serious miscommunication, and 14% who did not feel victimized by the experience). There were a small number of women whose experiences did not legally qualify as rape who nevertheless viewed their experience as rape including 1% of the victims of sexual contact, 3% of the victims of sexual coercion, and 3% of the victims of attempted rape. They were not used in the analysis. The analyses to predict Beck Depression score and Trait Anxiety score included all women who had been victimized to any degree (N = 1,721).

#### Yictim Conceptualization of the Experience

All early experience variables except Family Violence and Suicide History significantly predict a victim's label for rape (F=12.08, g=.000). Together the early experience variables account for 6.9% of the variance in victim label. With early experiences controlled, the psychological variable Rape Supportive Beliefs significantly predicts a voctim's label for rape (F=14.57, g=.000). The psychological variables themselves account for 3.9% of the variance so that together with early experience variables, 10.8% of the variance is accounted for. With earlier variables controlled, current behavior variables significantly predict victim label (F=14.08, g=.000). Current behavior variables add 2% of the variance raising the total variance accounted for to 12.8%. With all earlier variables entered first, assault characteristics significantly predict a victim's label for her rape (F=33.34, g=.000). The assault characteristics account for 23% of the variance which results in a total of 35.8% of the variance accounted for by 8 variables.

## State Anxiety Score

The State Anxiety score can be significantly predicted by the early experience variables of Family Violence and Suicide History (F=58.55, p=.000). Together these two variables account for 6.5 % of the variance in anxiety. With early experiences controlled, psychological characteristics significantly predict anxiety (F=163.70, p=.000). The psychological variables themselves account for 26.5% of the variance so that together with early experience variables, 33% of the variance in anxiety score is accounted for. With earlier variables controlled, current behavior variables significantly predict anxiety (F=120.18, p=.000). Current behavior variables add 3.1% of the variance raising the total variance accounted for to 33.1%. With all earlier variables entered first, the assault characteristics of Support and Severity significantly predict a victim's label for her rape (F=115.95, p=.000). The assault characteristics account for 2.6% of the variance which results in a total of 35.7% of the variance accounted for by 9 variables.

## Beck Depression Score

All early experience variables except Treatment History significantly predict a victim's depression score ( $F=41.21,\,p=.000$ ). Together the early experience variables account for 8.9% of the variance in victim label. With early experiences controlled, psychological characteristics significantly predict depression score ( $F=60.26,\,p=.000$ ). The psychological variables themselves account for 11.2% of the variance so that together with early experience variables, 20.1% of the variance is accounted for. With earlier variables controlled, current behavior variables significantly predict depression ( $F=55.00,\,p=.000$ ). Current behavior variables add .07% of the variance raising the total variance accounted for to 20.6%. With all

Item No. 12. (Results)

earlier variables entered first, assault characteristics significantly predict depression score (F = 48.70,  $\varrho$  = .000). The assault characteristics account for .03% of the variance which results in a total of 21.1% of the variance accounted for by 12 variables.

#### **DISCUSSION AND CONCLUSIONS**

Although difficulties were encountered with institutional resistance to the study, at the level of individual subjects the participation rate was almost 100%. The sampling procedures used in the study were successful in yielding a selection of subjects who represented quite well the U.S. higher education population. The major deficiency in the sample was the underrepresentation of the West. However, examination of weighted and unweighted data revealed that the impact of the underrepresentation on estimates of prevalence was minimal.

The procedures resulted in extensive data regarding early experiences, sexual experiences, psychological characteristics, and current behavior from 6,104 persons. These data were analysed in an attempt to address the four major goals that the study was funded to accomplish including:

- (1) To establish that college students are a high risk population for rape and other forms of sexual aggression,
- (2) To develop a descriptive picture of sexual aggression and victimization based on both hidden and identified victims and offenders,
- (3) To determine if sexually aggressive men can be differentiated from sexually nonaggressive men and if sexually victimized women can be differentiated from nonvictimized women, and
- (4) To predict the emotional impact of sexual victimization by acquaintances upon the victim.

The analysis of a data set of this magnitude is a lengthly process. It was not possible at this time to present definitive analyses that fully tap the potential of the data set. The analyses that were used were designed to reduce the data as much and as quickly as possible, and to establish the viability of lines of inquiry for future detailed exploration. The analyses that were reported were designed to allow theory testing and hypothesis generating. At a later stage, the broad and extensive data set will support analyses designed to build theory. A discussion of the results and implications of the analyses directed toward each of the study goals is presented in the following sections.

### Hidden Rape: An Epidemic

#### Previous Findings on Unreported Victimization

The FBI defines forcible rape as, "carnal knowledge of a female forcibly and against her will," and reports that 77,763 such occurrences occurred in 1983 (U.S. Department of Justice, Uniform Crime Reports, August, 1984). However, these figures greatly underestimate the true magnitude of rape since they are based only on reported instrances. Forcible rape is believed to be one of the most underreported of major crimes against the person (Uniform Crime Reports, 1982, p. 14). Official victimization studies suggest that the number of rapes that go unreported exceeds the number that are reported (Law Enforcement Assistance Administration, Criminal Victimization in Thirteen American Cities, 1975; United States Department of Justice, Criminal Victimization in the United States, 1982, Table # 90 "Percent distribution of victimizations, by type of crime and whether or not reported to the police," p. 70).

GRANT NUMBER R01-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 12. (Discussion)

In the typical victimization study, the residents of a standard sampling area are interviewed in their homes or by telephone and asked to indicate those crimes of which they or anyone else in their household have been victims during the previous year. Positive responses to screening questions result in the administration of detailed incidence questions to obtain depth information about the victimization. The screening question that triggers depth investigation about rape is the following: "Did anyone try to attack you in some other way" (i.e., other than "beat you up, attack you or hit you with something such as a rock or bottle, knifed, shot at, or attacked with some other weapon, threaten to beat you up, threaten you with a knfe, gun, or some other weapon," United States Department of Justice, Criminal Victimization in the United States, 1982, "Household Screen Questions," page 82). There are several assumptions in this approach to identifying unreported rapes that should be examined.

A primary difficulty is that rape is placed in a criminal justice context and recall of the experience is assumed to be triggered by the words "attacked in some other way." Requiring the respondent to infer the area of inquiry is problematic. Furthermore, the approach is based on the assumption that raped women conceptualize their experience in the context of other criminal victimizations that have or could have happened to them. Much has been written about the existence of a rape supportive belief system (e.g., Brownmiller, 1978; Burt, 1980; Weis & Borges, 1973). This belief system consists of culturally transmitted ideas about men, women, sexual relationships, and interpersonal violence, as well as widely accepted false beliefs about rape (e.g., rapists are always strangers, you cannot rape an unwilling woman, women are responsible for setting sexual limits). Previous research (Koss, 1985) has demonstrated that there are many women who have had experiences that meet legal definitions of rape who, for various reasons, do not conceptualize their experience as rape or view it in a criminal context.

A second difficulty with victimization studies is that they adhere to legal definitions of rape which are typological. A subject is either a rapist, a rape victim or a comparison subject. While this approach may be legical in the collection of crime statistics, it is less appropriate for studies with a mental health focus. If rape itself has a traumatic emotional impact, lesser degrees of sexual victimization might also be expected to produce wome degree of psychic trauma. Recently, several writers have suggested that a dimensional view of rape be adopted (e.g., Weis & Borges, 1973; Koss & Oros, 1982; Koss & Gidycz, 1985). In this framework, rape represents an extreme behavior but one that is on a continuum with normal male behavior within the culture. Sexual aggression is a general term that refers to a continuum of sexual activity including sexual contacts, sexual coercion, and sexual intercourse when obtained through threat or force without consent. Sexual victimization refers to a corresponding continuum of sexual victimization that women experience as a result of male sexual aggression.

A final concern with the definition of rape within victimization studies is the time period that is considered. Official crime statistics and victimization studies report <u>incidence</u> figures that indicate how many women were victimized by rape during the previous 6 months or one year. Indidence figures suggest how many new rapes can be expected to occur in a year and from this rate the need for criminal justice services, hospital emergency, and rape crisis services can be extrapolated. However, for studies with a mental health focus, <u>prevalence</u> figures seem to be more appropriate. Prevalence data reflects the number of women who have ever in their lives been rape victims. They seem more appropriate for clinicians to gauge the scope of the problem

GRANT NUMBER R01-MH-31618

## FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No. 12.

12. (Discussion)

of rape because long-term emotional aftereffects can be expected to remain mental health concerns beyond a 12 month period. In fact, the discussion of the post-traumatic stress disorder in the <u>Diagnostic and Statistical Manual of Mental Disorders</u> (American Psychiatric Association, 1980) specifically states, "It is not unusual for symptoms to emerge after a latency period of months or years following the trauma" (p. 237).

There have been several studies that have attempted to estimate the prevalence of rape without incorporation of the limiting assumptions of the criminal victimization study. Kanin and presented survey data that supported the colleagues (e.g., Kirkpatrick & Kanin, 1957) existence of sexual aggression/victimization among "normal" college students. However, their work is subject to methodological problems (i.e., the items are ambiguously worded, the sample was not random) and is over 20 years old. Koss and colleagues (e.g., Koss, 1985; Koss & Oros, 1982; Koss et. al., 1985) have presented more recent data data derived from behaviorally specific items. They found that 13% of female college students reported an experience that met legal definitions of rape. However, their data are restricted in generalizability since they were based on a sample representative of only one institution of higher education. Russell (1984) studied the prevalence of rape and lesser degrees of sexual victimization among a probability sample of 930 adult women living in San Francisco. Women were interviewed in their homes by trained female interviewers, and were asked to describe any unwanted sexual experiences that they had had. Later, the interview protocols were examined and instances were counted that involved "forced intercourse or intercourse obtained when the woman was drugged, unconscious, asleep, or otherwise totally helpless and unable to consent." Russell (1984) reported that 22% of the women reported such experiences and another 22% reported attempts to obtain unwanted intercourse. In total, 44% of these adult women reported victimizations that could be labeled rape or attempted rape. The major difficulty with Russell's work is that is is restricted in generalizability to a major urban area that may not be reflective of other parts of the country.

Kilpatrick and colleagues (Kilpatrick, Veronen, & Best, 1984) reported the results of a telephone survey of a random sample of 2,004 adult women residents of Charleston County, South Carolina. Although their survey included screening questions that were much more behaviorally specific than those used in the National Crime Survey, the items were still more vague and ambiguous than those used in other studies. In addition, the items regarding sexual assault were placed in the context of questions about other crimes and the entire survey was presented to respondents as an official government study of criminal victimization. Therefore, it is not surprising that the rates of rape and attempted rape found by these researchers were 5% and 4% respectively, considerably less than the rates reported in other recent studies (Koss & Oros, 1982; Koss, 1985; Russell, 1984).

## The True Scope of Victimization

In the present study, behaviorally specific items regarding rape and lesser degrees of sexual victimization were presented to a nationally representative sample of women in a noncriminal justice context and in a form that allowed determination of both prevalence rates since age 14 and previous year incidence. The results indicated that 15.3% of adult women with an average age of 21 reported an experience since the age of 14 that met legal definitions of rape. An additional 11.8% of the women reported experiences that were equivalent to attempted rape. Thus, a total of 27.1% of college women had been victims of rape or attempted rape. And, it should be noted that these women are far from having lived through the "risk period" for rape which must be

GRANT NUMBER
RO1-MH-31618

Item No.

12. (Discussion)

considered to last throughout life. In inferior

The rate of victimization was highly robust in that it did not vary from large to small schools, across types of institutions, or among urban areas, medium sized cities, and rural areas. The rate of victimization was found to be significantly different among the various ethnic groups and regions of the country. Because ethnicity and region may be correlated in the sample, further study will be required to interpret the finding. At this point, it is safe to conclude only that some ethnic groups appear to be at higher risk for sexual victimization than others. Perhaps even more alarming that the overall prevalence rates was the finding that women were reporting multiple experiences with sexual victimization. Yirtually all forms of sexual victimization had occurred, on average, more than twice to victimized women. Only 5% of the rapes that were reported in the study ever came to the attention of criminal justice authorities in spite of the fact that almost half of the victims viewed themselves as victims of some crime (27% viewed their eperience as rape, 16% viewed their experience as a crime but not rape).

These findings establish the existence of "hidden rape" and suggest the magnitude of the problem. They transform rape and lesser degrees of sexual victimization from heinous but rare events into normative experiences in the lives of women. At these epidemic proportions, the potential of rape as a tool of social control that can serve to maintain differential power relationships between men and women in our society cannot be ignored.

### Undetected Rapists: Previous Findings

The detection of sexually aggressive men is a critical methodological issue. Since extreme forms of sexual aggression constitute criminal acts, one cannot simply ask male subjects if they have ever committed rape or attempted rape. Such a question would likely receive an unanimous negative response; even convicted rapists minimize the severity of their sexually assaultive acts or completely deny them. As Weis and Borges (1973) stage, "If the man can call the act seduction, he may call himself a winner; if it is rape, he is a loser" (p. 87).

The most common method of selecting a sample has been to utilize males who have been identified as rapists through judicial procedures. Convicted rapists have been studied both prior to sentencing and following incarceration or institutionalization. A primary problem with this sampling procedure is that the subjects may not be representative of the entire population of rapists. It has been estimated that for every rape reported, 3-10 rapes are committed but not reported (Law Enforcement Assistance Administration, 1975). Only a fraction of these reported rapes will eventually result in a conviction. For example, Clark & Lewis (1977) suggested that after allowances are made for nonreporting, the inability by police to acquire evidence, nonapprehension, and failure to convict, the highest justifiable proportion of actual rapists who are ever found quilty is 7%. At each stage of the judicial process, a portion of the potential rapist sample is excluded from systematic study. However, factors other than judicial ones may exclude persons from prosecution or may influence the verdict. For example, it has been argued that a rapist who knows the victim may be at less risk for being reported or convicted of rape than a rapist who is a complete stranger to the victim (e.g., Clark & Lewis, 1977). Similarily, certain demographic or psychological characteristics (e.g., social class, ethnicity, intelligence, presence of mental disorder) may facilitate prosecution and conviction. As a result, psychological characteristics of convicted rapists may reflect as much about the judicial process as about the dynamics of sexual aggressionn. Brodsky (1976) concluded, "It is not known if nonaprehended

Item No. 12. (Discussion)

assailants are like those who make it through the justice system's progressive filtration process" (p. 5).

Two alternative methods to judicial identification have been used in the study of sexual aggression. Malamuth's (1981) approach has been to focus on men who have the potential to commit rape, rather than attempt to identify men who have actually raped. A male subject is asked to rate the liklihood that he would rape a female if he could be assured that he would not be apprehended or punished. Any man who admits to a likelihood above "not at all likely" is assumed to possess a propensity to rape. Approximately 35% of male college students admit to some degree of liklihood of raping. Koss and colleagues (1985) employed a self-report survey t hat consisted of behavioral descriptions of various acts of sexual aggression that varied in the amount of coercion and force that were present. The term " rape" was not used. They reported that 4.3% of a representative sample of men from one institution of higher education revealed behavior that would legally qualify as rape. Twentyman (1978) studied "undetected rapists" by advertising for subjects who had raped and were willing to discuss their experiences with an interviewer. However, this approach is problemmatic since it has been demonstrated that a most men who have engaged in rape do not view themselves as rapists. Also, all of the research reviewed above is extremely limited in its generalizability since it is based on small and restricted samples of men.

## The Scope of Undetected Rape by College Men

In the present study, behaviorally specific items regarding rape and lesser degrees of sexual aggression were presented to a nationally representative sample of men. The items were presented in a noncriminal justice context and in a form that allowed determination of both prevalence rates since age 14 and previous year incidence. The results indicated that 4.6% of adult men with an average age of 21 reported a sexually aggressive act since the age of 14 that met legal definitions of rape. An additional 3.2% of the men reported an act that was equivalent to attempted rape. Thus, a total of 8.9% of college men have perpetrated acts of rape or attempted rape. And, it should be noted that these men are far from having lived through the "risk period" for raping which must be considered to last throughout life.

The rate of sexual aggression was highly robust in that it did not vary from large to small schools, across types of institutions, or among urban areas, medium sized cities, and rural areas. The rate of sexual aggression was found to be significantly different among the various ethnic groups and regions of the country. Because ethnicity and region may be correlated in the sample, further study will be required to interpret the finding finding fully. At this point, it is safe to conclude only that some ethnic groups appear to be more likely to report sexually aggressive acts than others. Perhaps even more alarming that the overall prevalence rates was the finding that men were reporting multiple acts of sexual aggression. All forms of sexual aggression had been perpetrated between 2-3 times by sexually aggressive men. Only 2% of the perpetrators of rape ever came to the attention of criminal justice authorities and it was very unlikely that they would label their own behavior as rape. In fact, 84% of the rapists indicated that their behavior definitely was not rape.

Review of incicdence reports by college men and women indicate that the number of assaults admitted by men isn't sufficient to account for the number of victimizations experienced by women. Yalidity studies undertaken in the present project suggested that most of the sexually

ADM-442 IRev

Item No.

12, (Discussion)

aggressive acts reported by men can be substantiated upon interview. However, it was not determined whether detailed interviewing might reveal additional incidents not reported spontaneously by the man. It is possible that exploration of a man's "seductions" would reveal instances where the behavior could have been viewed as "forceful" but the man did not conceptualize his own behavior as forceful. This speculation is supported by anecdotal reports that "date rapists" can almost always pass lie detector tests because they truly do not see the incidents as rape and do not perceive their force as beyond the limits of normal behavior.

In conclusion, college students are intelligent, educated, integrated into the social order, and socially advantaged. Yet, these findings are a sad commentary on the quality of their sexual knowledge and interpersonal relationships. If college men resort to force to obtain sexual relationships, one can only speculate what would be revealed in a study of a national sample of men.

### Hidden Rape: A Closer Look

A large amount of descriptive data on the early experiences, psychological characteristics, current behavior, and assault characteristics of college students was reported. These data allowed a fascinating look at the group of people who make up the higher education population. These data also allowed the construction of a "portrait" of the typical rape experienced by college women, the typical rape reported by the college man, and the background and personality of the victims and perpetrators. The descriptive data were used for two purposes. First, they were used to estimate the practical significance of statistically significant differences in the development of the reduced set of variables used in later analyses. Second, and perhaps most importantly, the descriptive data allow anecdotal reports of sexual aggression and victimization among college students to be placed in perspective. For example, a recent article on date rape in Newsweek began with a case report in which a woman was repeatedly raped by her boyfriend with a broken coke bottle. Comparison of this case with the present study's descriptive portrait of victimizations reveals that it is exceedingly misleading and misrepresentative. Few date rapes reported by a national sample of 477 rape victims involved weapons or more than moderate force.

The descriptive portraits also allow informal speculation about differing perspectives of men and women in sexually aggressive situations. Of course such comparisons are problematic because the assaults to which the men refer are not entirely the same episodes as the victimizations reported by women. Some rapes occurred before college age and some perpetrators were not college students. However, it can be assumed that there is significant overlap between the rape incidents experienced by college women and perpetrated by college men. There are many dimensions on which the reports are quite consistent such as the relative proportion of single to multiple rapes, the proportion of stranger to acquaintance rapes, the prevalence of date rape, the social context and physical location in which the assault took place, the use of intoxicants by the perpetrator, the age at which the episodes occurred, the obliviousness of the man to the woman's resistance, whether the episodes were reported to police and whether the parties had sex again on a subsequent occasion.

There are also many dimensions on which extreme divergence in the perceptions of the victim and perpetrator are noted. For example, victims viewed their nonconsent as extremely clear, the man's force and their own resistance as moderately intense, their prior intimacy as petting

A CONTRACTOR OF A CONTRACTOR O

) dr. trope 1

Item No.

12 (Discussion)

only above the weist, and the man's being much more responsibility for what happened than they were. Nearly half of the women viewed themselves as the victims of rape or another crime. Perpetrators viewed the victims lack of consent as definitely unclear, their own force and the victim's resistance as minimal, prior intimacy beyond petting below the waist, and the woman as more responsible for what happened than they were. Whereas victims were scared, angry, and depressed; perpetrators' primary emotion was pride. In spite of the fact that one-third of the perpetrators noticed that the victim physically struggled or reasoned and pleaded with them to stop, only 1 man out of 131 perpetrators viewed his behavior as rape.

These findings emphasize that women's views regarding the severity of the problem of sexual assault are not likely to be shared by the men who perpetrate assaults. They suggest that preventitive and educational programs on rape cannot begin with the assumption that a shared perception exists of the magnitude of the problem of sexual assault. The findings also highlight the extreme amount of resistance among men to labeling as rape any sexual behavior that occurs within a social relationship.

Risk Profiles for Sexual Aggression and Sexual/Victimization

Yulnerability to Victimization: Previous Findings

Three theoretical models attempts to explain how women become rape victims. The victim precipitation model suggests that vulnerability to rape can be increased unknowingly by specific behaviors or personality characteristics of a woman such as passibity, oversubmissiveness, or insensitivity to social nuance. The social control model states that women are socialized through sex-role training to accept rape supportive beliefs and attitudes which may increase their likelihood of sexual assault. Finally, the situational biarne model suggests that sexual assault is made more likely by certain environmental or structural circumstances surrounding the assault such as the location or social context of the interaction.

Empirical support for all three models is extremely sparse. The victim precipitation model was promulgated by Amir (1971) who based his views on the observation that some police reports on rape noted that the victim "had a bad reputation" in the neighborhood. He reasoned that the victim could be considered to have precipitated her own rape by engaging in behavior that led to a bad reputation. Kanin (1957) used as support for victim precipitation the observation that highly sexually aggressive men sometimes justify their assaultive behavior by blaming the provocativeness of the woman's dress or her flirtaciousness. A variation of victim precipitation. labeled a vulnerability model, has also received empirical study. Selkin (1978) studied personality differences between "rape resistors" and rape victims and found that successful resistors scored significantly higher on several California Psychological Inventory scales including dominance, social presence, sociability, and communality. Myers, Templar and Brown (1984) administered these scales among others to a sample of rape crisis center clients and women matched for demographics who were recruited on college campuses. They concluded that the victims' likelihood of being raped had been increased by personality characteristics including greater passivity and lesser poise in social situations. Koss (1985) noted that these studies are based on small samples of reported rape victims and cannot be viewed as generalizable to all rape victims. She studied the personality characteristics of a sample of 62 rape victims recruited by self-report survey from a college student population and compared them to 87 women who were victimized to lesser degrees and 82 women who had never been sexually victimized. No

GRANT NUMBER ROL-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

12. (Discussion)

personality differences were found among the groups. All women, including the rape victims, scored above college student means for social poise and dominance.

The social control model of victimization has been explored in a number of studies that have examined the acceptance of rape supportive beliefs among various groups such as citizens (e.g. Burt, 1980), police officers, and rape crisis counselors (e.g., feild, 1978). Shotland and Goodstein (1983) concluded that one component a rape supportive belief system, attitudes toward women, was a significant predictor of the liklihood a college women would view a senario portraying sexual aggression among acquaintances as rape. However, Koss (1985) reported no significant differences between raped women, women victimized to lesser degrees, and sexually nonvictimized women on the five components of the rape supportive belief system. Thus, there currently exist insufficient data to conclude that rape victims adhere to extreme rape supportive beliefs that render them uniquely vulnerable to rape.

The situational blame model has been explored in studies of rape avoidance (i.e., Block and Skogan, 1982; Bart & O'Brien, 1981, 1984; Javorek, 1979; McIntyre, 1979; Queen's Bench Foundation, 1976; and Sanders, 1980). In these studies victims of attempted rape are considered to have avoided rape. Their initial response strategies are compared to those of rape victims to determine if any forms of resistance predict rape avoidance. For example, Javorek (1979) found that whether the potnetial victim screamed for help or not was the most useful predictor of whether a rape attempt was completed. Koss (1985) reported a small cluster of situational variables that differentiated acknowledged rape victims from unacknowledged rape victims (women who had had a sexual assault that met legal definitions of rape but who did not conceptualize their experience as rape). Unacknowledged rape victims were much more likely than acknowledged victims to be closely romantically acquainted with the perpetrator and to have shared extensive prior consensual sexual activity with him.

#### **Yictimized Versus Nonvictimized Women**

In the present study, planned comparisons were conducted between the groups of sexually victimized women and the comparison sample of nonvictimized women. In the analysis, groups of variables were ordered in time and entered in steps. The effects of earlier variables that could significantly predict later variables were controlled in the analysis. The results indicated that all groups of victimized women were significantly different from nonvictimized women on most of the variables that were included in the study with the exception of the psychological variables. Specifically, all groups of victimized women differed from nonvictimized women in early experiences. The most clearcut differences occurred on the variables reflecting family violence, childhood sexual abuse, and early initiation of sexual activity. This finding is consistent with recent theoretical discussions of the link between childhood sexual abuse and increased vulnerbility to sexual victimization in adulthood (Finkelhor & Browne, 1985).

All victimized women differed from nonvictimized women in current behavior. Yictimized women were characterized by a higher frequency of alcohol use, larger quantities drunk, and more frequent intoxication. In addition, they demonstrated a higher number of sexual partners and required less intimacy between partners before they approved of sexual intercourse than nonvictimized women. The current behavior variables could be viewed as exposure variables. A woman's risk of sexual victimization may rise as her exposure increases to sexual partners and to situations where alcohol is used. These findings support contentions that certain

Item No.

IN DE STATE OF THE STATE OF THE

12. (Discussion)

situational variables foster the occurrence of sexual assault.

Clear differentiations between the groups failed to occur on the psychological variables. Rape victims and victims of sexual coercion scored differently than nonvictims on Rape Supportive Beliefs. However, the victims were characterized by <a href="less">less</a> acceptance of Rape Supportive Beliefs. Victims did not score in a more feminine direction than nonvictimized women. All victims also differed from nonvictims on the Androgeny measure. However, the victim groups' means were less than one point lower than the college student female mean and only .25 standard deviation from the mean. Thus, the difference may lack practical or clinical significance. There findings are contrary to predictions of the social control model of rape. These findings challenge assertions that traditional socialization of women creates a special vulnerability to rape. The present study failed to support the existence of women rendered "safe victims" by virtue of their belief in stereotypes about rape.

Planned comparisons were also conducted within the victimized women using the victims of sexual coercion as a comparison sample. The pattern of results was consistent with the comparisons reported above. The groups of victims differed on all of the early experience variables, none of the psychological variables, and most of the current behavior variables. It is important to note that victims of sexual coercion did not differ from victims of rape on either current behavior variable: sexual behavior of alcohol/drug use. This finding suggests that while current behavior may increase a woman's exposure to victimizing situations, it does not predict the degree of victimization sustained. Other factors, particularily perpetrator variables must be considered.

Rape victims, attempted rape victims, and sexual contact victims were different from the victims of sexual coercion on the assault variables. Compared to other types of sexual victimization, sexual coercion was characterized by more intimate acquaintanceship between victim and perpetrator, greater number of assaults by the same man, and more consentual intimacy prior to the assault. Sexual contact and sexual coercion did not differ in severity. However, there were large differences on severity and support between sexual coercion, attempted rape, and rape. Rape was characterized by greater force by the perpetrator, more resistance by the victim, less impact of resistance, and more negative emotions at the time of assault, and a less positive, perceived reaction postassault. This pattern of results, especially on the severity variables, is consistent with a dimensional view of sexual victimization and supports the linear ordering of groups that was used in the present study.

## Theoretical Models of Raping: Previous Findings

There are two general theoretical perspectives on the causality of male sexual aggression. The psychopathology model suggests that emotional maladjustment may lead an individual to commit rape. In contrast, the social control/social conflict model proposes that offenders maintain rape supportive beliefs that are reinforced by the differential power distribution between men and women in our society. These beliefs are hypothesized to allow offenders both to engage in and to justify the crime of rape. In addition to these two general perspectives, research on rapists has also focused on deviant sexual arousal patterns as well as hostility to women as causal factors of rape.

74

Item No.

12. (Discussion)

Psychopathology. Traditionally, it has been assumed that men who rape are psychologically maladjusted individuals. Psychological tests of convicted rapists have provided inconclusive support for this position however. Perdue and Lester (1972) found no differences between the Rorschach records of rapists and prisoners who had committed aggressive but nonsexual offenses. Studies that have utilized the Minnesota Multiphasic Personality Inventory (MMPI) provide no evidence for the presence of neurotic or psychotic psychopathology among rapists but do suggest elevations on scale 4 (Psychopathic Deviate). However, rapists typically do not differ from other criminal piopulations on this scale (e.g., Rader, 1977). Thus, there is no empirical support for the presence of diagnosible psychopathology among rapists although evidence of personality disorder has been reported consistently. While these studies are methodologically superior to earlier studies (e.g., Cohen, Garofalo, Boucher, & Seghorn, 1971; Groth, Burgess, & Holmstrom, 1977) which were impressionistic and included no measures or statistical treatment of variables, several problems remain including the failure to control for demographic variables that lead to spurious elevation on the MMPI (e.g., age, ethnicity, socioeconomic status). In addition, these studies are plagued by the general problems with the use of judicially selected samples that were detailed in an earlier section. Koss and colleagues (1985) have examined the psychopathology of undetected rapists. They administered two scales sensitive to antisocial tendencies--Scale 4 of the MMPI and the Activity Preference Questionnaire (Lykken, Tellegen & Katzenmeyer, 1973) -- to college males who admitted behavior congruent with legal definitions of rape. The Activity Preference Questionnaire was developed in a state prison setting to differentiate psychopathic from nonpsychopathic prisoners. However, Koss et al. (1985) found it to be unrealted to the prediction of sexual aggression. The MMPI scale was significantly correlated with sexual aggression (r = .28) but it failed to add to the prediction of aggression beyond what could be accomplished through the use of attitude scores.

Attitudes. Several researchers have attempted to examine belief in stereotypes or myths about rape among diverse groups. Burt (1980) defined a rape muth as a "prejudicial, stereotyped, or false belief about rape, rape victims, and rapists" (p. 217). She has reported strong relationships between the acceptance of rape muths and other deeply held beliefs such as sex-role stereotypes, sexual conservatism, adversarial sexual beliefs, and acceptance of interpersonal violence. Feild (1978) administered an Attitudes Toward Rape questionnaire to rapists committed to a state mental hospital. On the basis of a factor analysis of the questionnaire, eight factor scores were computed for the subjects. On every factor, rapists were significantly different from rape crisis counselors. They differed from police officers on four of the factors and from citizens on five of the factors. On the other hand, Scully and Marolla (1982) found no significant differences in attitudes between incarcerated rapists and nonrapist incarcerated offenders. Koss and colleagues (1985) reported that college student rapists could be discriminated from less sexually aggressive men by seven variables including six rape supportive belief factors based on Burt (1980). Several studies have found a relationship between rape supportive beliefs and liklihood of raping (e.g., Briere & Malamuth, 1983; Malamuth, Haber, & Fesbach, 1980; Malamuth, 1981, Malamuth & Check, 1983, Tieger, 1981). Ageton (1984) reported the results of a study of sexually aggressive adolescents who were identified through screening questions on the National Youth Survey. This study began in 1976 and utilized a longitudinal, panel study of a national probability sample of youth aged 11 to During a standardized interview in the context of other crime questions, subjects were asked how many times in the last year they had attempted or had sexual relations with someone against their will. A sample of 68 sexually aggressive adolescents were identified whose assaults had occurred between 1978-1980. Among the data available on the youth were attitude measures. A

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

12. (Discussion)

strength of the study is that due to panel design, the attitude measures were administered prior to the reported sexual assaults. Results suggested that four variables correctly classified 77% of the subjects: involvement with delinquent peers, crimes against persons, attitudes toward rape, and family normlessness. However, involvement with delinquent peers alone could correctly classify 76% of the subjects. In general, the results of studies on diverse populations including incarcerated rapists, sexually aggressive youth, sexually aggressive college students, and men likely to rape support the hypothesis that certain attitudes and beliefs about rape are associated with the occurrence of sexual aggression.

Early studies of sexual arousal in sexually aggressive men utilized Deviant Arousal. retrospective self-reports of the individual's response to pornography (e.g., Thorne & Haupt, 1966; Gebhard, Gagnon, Pomeroy & Christensen, 1965) or estimated sex drive (Kanin, 1965). These studies failed to produce a consistent set of differences between rapists and nonrapists. Later studies have utilized more mojective measures of sexual arousal and penile erection. Abel, Barlow, Blanchard, and Guild (1977) compared objectively measured sexual arousal in a group of rapists compared to a group of nonrapists (composed primarily of bisexuals and pedophiles) and presented an audiotaped senario of mutually consenting intercourse and one of forcible rape. The penile enlargement measure indicated that nonrapists were less aroused to the rape depiction than to the mutually consenting intercourse. Rapists, on the other hand, were equally aroused to these two senarios. In a second study, penile enlargement of wapists was assessed to an aggressive senario devoid of sexual content. While the degree of erection was considerably less to the aggressive scene than to the rape or mutually consenting scenes, a significant correlation was noted between a rapist's response to the aggressive cues and his response to the rape cues ( r= .98). These findings led the authors to suggest that the observed level of sexual arousal to rape scenes was the result of an individual's response to mutually consenting intercourse and to aggression. They hypothesized that in the nonrapist the presence of aggressive cues inhibited arousal, while in rapists, there was no appreciable inhibition. Subsequent studies with verbal depictions (Barbaree, Marshal, & Lanther, 1981) and movies (Hinton, O'Neill, & Webster, 1980; Quinsey, Chaplin, & Yarney, 1981) have been generally supportive of these conclusions. Melamuth and Check (1980s, 1980b, 1981) have reported similar findings with group of males with a proclivity to rape. Barbaree et al., (1979) conclude, " ... Sexual arousal in thee rapists may have been deviant, not necessarily because force and violence and nonconsent of the female evoked their sexual arousal, but perhaps becasue force, violence, and nonconsent of the female failed to inhibit their sexual arousal" (p. 221).

Hostility toward Women. Less attention has been directed to the study of the hostile motivation of rapists as compared to their sexual arousal. Three studies have compared incarcerated rapists on measures of hostility. Fisher and Rivlin (1971) reported that rapists scored lower on the California Psychological Inventory Aggression scale than did other prisoners or normal controls. Scully and Marolla (1982) found no significant differences between rapist and nonrapist prisoners on a Hostility toward Women scale. In contrast, Rada, Laws, and Kellner (1976) found that rapists scored higher than a normal group or child molesters on the Buss-Durkee Hostility Inventory. Kanin (1965) found that sexually aggressive men scored higher on the Zaks and Walter's Aggression scale. Koss et al., (1985) reported that the total score on the Buss-Durkee Hostility Inventory was correlated with level of aggression (7=.17) but did not significantly contribute to the prediction of group membership. These studies all utilized self-report measures of hostility. Actual harming behavior was studied by Malamuth (1981) who assessed the reported likelihood of raping of male college students; then several days

Item No. \_\_\_12. (Discussion)

later a female experimenter insulted them. Subsequently, the men were asked to administer different levels of aversive noise to the female experimenter. The results indicated that men characterized by a high liklihood of raping were more behaviorally aggressive toward the woman, felt more angry at her, and reported a greater desire to hurt her than men characterized by low liklihood of raping.

## Sexually Aggressive Versus Sexually Nonaggressive Men

In the present study, planned comparisons were conducted between the groups of sexually aggressive men and the comparison sample of sexually nonaggressive men. In the analysis, groups of variables were ordered in time and entered in steps. The effects of earlier variables that could significantly predict later variables were controlled. The results indicated that all groups of sexually aggressive men were significantly different from sexually nonaggressive on all three sets of variables used in the study. Specifically, all groups of sexually aggressive men differed from sexually nonaggressive men in early experiences. Clearcut differences occurred on the variables reflecting family violence and childhood sexual abuse, and early initiation of sexual activity. This finding is consistent with recent theoretical discussions of the link between childhood sexual abuse and adult male sexual aggression (Finkelhor & Browne, 1985). Finkelhor and Browne theorize that one of the effects of child sexual abuse is a sense of powerlessness which is linked to the fear and anxiety engendered by the child's inability to control the noxious events. "In reaction to powerlessness, some sexual abuse victims may have unusual and dysfunctional needs to control or dominate. This would seem particularly to be the case for male victims, for who issues of power and control are made very salient by male sex role eocialization" (p. 536).

With early experiences controlled, all sexually aggressive men differed from sexually nonaggressive men on psychological characteristics including MMPI Scale 4 and Hostility toward Women. Rapists and attempted rapists differed from sexually nonaggressive men on Rape Supportive Beliefs as well. These results are consistent with previous research on psychopathology, attitudes, and hostility among rapists and other sexually aggressive men. Subsequent analyses will be required to examine the relative predictive power of each of these psychologicial measures.

All sexually aggressive men differed from sexually nonaggressive men in current behavior. Compared to sexually nonaggressive men, sexually aggressive men were characterized by a higher frequency of alcohol use, larger quantities drunk, more frequent intoxication, more frequent reading of male-oriented magazines, associations with men who typically consider women as sex objects, a higher number of sexual partners, and a less intimacy required between partners before they approved of sexual intercourse. The current behavior variables could be viewed as "releasers," that is variables that allow a man to overcome internal inhibitions against sexual aggression (Finkelhor & Browne, 1985). The chances of a man, predisposed to sexual aggression by abusive early experiences and psychological characteristics, assaulting a female partner may be increased by environmental factors such as pornographic magazines which encourage the objectifying of women and reduce inhibitions over sexual violence, associations with peers who encourage viewing and treating women as sex objects, and use of alcohol/drugs which reduce judgement and impulse control.

ADN 447 18 PV

Item No. \_\_

12. (Discussion)

Planned comperisons were also conducted within the sexually aggressive men using the sexually coercive men as a comparison sample. The comparison of rapists to sexually coercive men is most informative since these two groups both obtained sexual intercourse but rapists used force to obtain it while sexually coercive men used verbal manipulation and misuse of power. Although both forms of behavior are abhorrent to women, the use of violence clearly sets the rapists' behavior apart. Comparison of the two groups helped to specify what characteristics are Rapists differed from associated with sexual violence as opposed to sexual manipulation. sexually coercive men in early experiences. Specifically, rapists reported being beaten or hit by their parents more often than sexually coercive men. They did not differ in early abuse experiences. Rape versus sexual coercion was the only comparison within sexually aggressive men that revealed significant differences on psychological variables. Rapists were differentiated from sexually coercive men by greater scores on Rape Supportive Beliefs. They did not differ in their scores on MMPI Scale 4, Hostility toward Women, Masculinity, or Androgeny. On the current behavior variables, rapists differed from sexually coercive men in terms of exposure to releasers but not in sexual behavior. Thus, both groups of men had a relatively high number of sexual partners and low standards for required intimacy before they considered sexual intercourse acceptable. However, rapists read male oriented magazines "very frequently" compared to coercive men who read them "seldom." Rapists report drinking a significantly larger amount of alcohol when they drink than sexually coercive men did. Although further analyses will be required to explore the relative predictive power of the variables, these findings suggest that the most important determinants of the use of force in sexual situations may be a background of family violence, a rape supportive belief system, frequent use of reading matter that models and condones violence squinst women, and the drinking larger quantities of alcohol than other men.

The clear implication of these results is that an integrative model of rape is needed in order to account for the diversity of findings in the present study. Sexually aggressive men were differentiated from sexually nonaggressive men beginning with early family environment and experiences which were associated with later psychological differences. Then, releasing factors apeared to amplify and channel pre-existing predilections to abuse women. Finkelhor's (1984) model of four preconditions for child abuse (i.e., motivation to sexually abuse, overcoming internal inhibitors, overcoming external inhibitors, and overcoming the resistance of the child) may be a prototype for organization of an integrative theory. Further analyses of the present data will allow the development and testing of a theoretical model that integrates early experiences, psychological characteristics and current behavior to explain male sexual aggression.

#### The Trauma of Rape

### Research on Symptomatic Responses: Previous Findings

Most prospective empirical studies of the symptomatic responses to rape have focused on the time period between one month and one year postrape. Extensive reviews of this material are available (e.g., Ellis, 1983; Holmes & Lawrence, 1983). What is known is that most victims experience an immediate postrape distress response, which for some victims fails to resolve and develops into a chronic, through heterogeneous symptom pattern that may persist for a variable length of time (Ellis, 1983). The core features of these long-term symptom patterns appear to be a set of fear/avoidance responses, affective constriction, disturbances of

to diff expe

GRANT NUMBER RO1-MH-31618

#### FINAL REPORT GUIDELINES CONTINUATION PAGE

Item No.

12. (Discussion)

self-esteem/self-efficacy, and sexual dysfunction.

A number of factors may modify the intensity of a victim's response to rape including: Characteristics of the crime (McCahill, Meyer, & Fischman, 1979; Frank & Stewart, 1983), locus of control (Janoff-Bulman, 1979), coping ability (Burgess & Holmstrom, 1979), life stress (Ruch, Chandler, & Harter, 1980), personality vriables and social network (Atkeson, Calhoun, Resick, & Ellis, 1982), and developmental stage (Notman & Nadelson, 1976). No isomorphic relationship between traume and symptom has been observed. The nature of the interactive effects and why some victims develop more chronic patterns is not yet understood.

Resick (1983) noted that "Rape victims are frequently unwilling to receive any type of therapeutic intervention within the first few months after the assault. They (and their families) often express the hope that if they don't talk about the assault and try not to think about it, they will forget it and recover" (p. 131). Unfortunately, evidence from long-term follow-up studies with rape victims suggests that spontaneous recovery doesn't characterize the majority of victims. More than 40% of rape victims reported continued sexual difficulties, restricted going out, suspiciousness, fear of being alone, and depression 1 to 1 1/2 years postassault (Nadelson, Notmen, Jackson, & Gornick, 1982). Problems in long-term sexual functioning (e.g., Becker, Skinner, Abel, & Treacy, 1982; Burgess & Holmstrom, 1979) and in marital adjustment also have been reported (Miller, Williams, & Bernstein, 1982). Only 25% of rape victims were found to be free of significant symptoms on standard psychological tests one year after the assault (Kilpatrick, Yeronen, & Resick, 1979). One year after the rape, as a group, victims still scored one standard deviation above nonvictimized women on a fear survey. Burgess and Holmstrom (1979) interviewed rape victims four to six years after sexual assault and asked them if they "felt back to normal, that is, the way you felt prior to the rape." The responses indicated that 37% of the victims had felt recovered within months; 37% felt recovered only after several years, and 26% did not feel recovered. Thus, it is not surprising that in one sample of women raped 1-16 years previously, 48% stated that they eventually had to seek psychotherapy (Ellis, Atkeson, & Calhoun, 1979).

A major methodological note which must be sounded regarding the interpretation of the entire body of published literature on the traumatic aftereffects of rape is that all studies employed self-identified rape victims most of whom were seeking service at a rape crisis center. It is very likely that this group of victims differ in important ways from women who do not think of themselves as rape victims and/or do not seek victim assistance services. Specifically, in the present study the 93% of the offenders were acquaintances; 57% were dating the victim. Yet, in the published literature on rape aftereffects stranger rapes are most prevalent. For example, among the victims studied by Resick, Calhoun, Atkeson, and Ellis (1981), 57% were raped by total strangers compared to 2% who were dating the offender. Likewise, in the present study it was found that only 5% of rape victims utilized rape crisis center services whereas 42% of rape victims told no one about their experience. These observations support the need for the present study which extended the study of rape after affects to a sample, that included victims of acquaintance rape, victims who did not conceptualize their experience as rape, and victims who sought no services and told no one about the rape. In the present study measures of depression, anxiety, sexual satisfaction, and relationship quality were included to examine the traumatic impact of rape.

12. (Discussion)

## The Prediction of Anxiety Among Victimized Women

All groups of sexually victimized women differed from nonvictimized women on the Trait Anxiety Inventory. The nonvictim mean in the present study was the equivalent the 55th percentile in the published norms for college students. The rape victim mean was the equivalent of the 79th percentile. The mean score among rape victims exceeds the mean for hospitalized physically ill persons but does not reach the range of hositalized psychiatric patients. On average, college student women raped 1-2 years previously are more anxious than 79% of the women enrolled in higher education. The anxiety score could be significantly predicted by all the sets of variables used in the study including early experience, psychological characteristics, current behavior, and assault characteristics. A combination of 9 variables predicted 36% of the variance in anxiety scores. The largest proportion of variance (26.5%) was accounted for the the psychological characteristics, particularily androgeny and femininity. When the influence of psychological characteristics was controlled, assault characteristics contributed only an additional 2.6% of the variance.

## The Prediction of Depression Among Victimized Women

Depression scores on the Beck Depression Inventory increased linearly with severity of assault. Rape victims were significantly more depressed than all the other groups of women. Depth of depression categories have been provided to aid in interpretation of the Beck score (Beck et al., 1961, Bumberry, Oliver, & McClure, 1978). Scores of 0-9 indicate minimal or no depression; scores of 10-15 indicate mild depression; scores of 16-13 reflect moderate depression and scores of 23 and above are believed to reflect severe clinical depression. The rape victim mean can at most, be taken to reflect a very slight degree of depression that is far from attaining clinical significance. The depression score could be significantly predicted by all the sets of variables used in the study including early experience, psychological characteristics, current behavior, and assault characteristics. A combination of 12 variables predicted 21.1% of the variance in depression scores. The largest proportion of variance (11.2%) was contributed by psychological characteristics, particularily androgeny and rape supportive beliefs. When psychological characteristics were controlled, assault characteristics accounted for only an additional .3% of the variance.

## Sexual Satisfaction and Relationship Quality

Although these measures had been included in the study to reflect rape impact, results on them were not consistent with previous research on victims. For example, rape victims rated themselves as slightly more sexually satisfied than the other groups of women on petting and sexual intercourse. Previous research on sexual satisfaction among rape victims (Orlando & Koss, 1983) has cautioned about the high vulnerability to demand characteristics and expectancy effects of the usual methods of assessing sexual satisfaction in rape victims. Typically, a victim is asked to rate her satisfaction "currently" and "before the victimization." In the present study, the sexual satisfaction items were administered to all subjects and were placed early in the questionnaire before any questions about assaultive sexual experiences had occurred. Subjects were asked only to rate their current satisfaction. They were not asked to recall their sexual satisfaction in the period immediately following the rape. In the present group of women, victimized 1-2 years previously, there was no evidence of lowered sexual satisfaction among victims. All three items that measured relationship quality—the ability to trust others, the

ability to get close to others, and the ability to maintain relationships revealed significant differences between rape victims and nonvictimized women although the magnitude of differences was not large.

## Prediction of Label for the Experience

All the sets of variables used in the study including early experiences, psychological characteristics, current behavior, and assault characteristics could significantly predict the label a victim chose for her experience. With a combination of 8 variables it was possible to predict 36% of the variance. The largest contribution to prediction was made by assault characteristics which alone contributed 23% of the variance. Assault severity was particularily powerful in predicting the victim label. The more serious the assault, the more violence and resistance involved, the more likely a victim was to see the incident as rape. The higher the score on assault context which reflects the closeness of the relationship between the victim and offender, the less likely the label rape was to be used.

In summary, study of the impact of (acquaintance rape which occurred 1-2 years previously revealed evidence of a long-term impact. The most severe impact was found in anxiety. Even two years after the rape, victims were characterized by a persistent and enduring elevation in anxiety score that approached clinical significance. No evidence was found to support a long-term impact of rape on sexual satisfaction. Elevations on depression and relationship quality suggested slight impacts of rape in these areas. However, more indepth analysis of these data is planned. It was observed that the distributions on these variables were quite skewed. While on average the impact of rape was mild, on an individual basis some victims were having few problems and some victims were quite disturbed. Further analyses will according to the severity of impact and attempt to determine the set of variables that differentiate victims with severe impact from those with mild impact. It will be particularily important to learn whether victims with minimal impact use coping behaviors such as telling family and friends and seeking help from therapists or counselors. These findings would have practical therapeutic implications.

These findings of slight enduring aftereffects of sexual assault in a population of college students suggest that many women are coping well with the experience. This conclusion is consistent with recent work on cognitive adaptation which highlights the "normal" person's ability to adjust to traums. Taylor (1983) has observed that people are adaptable, self-protective, and functional in the face of setbacks. "The process of cognitive adaptation to threat, though often time-consuming and not always successful, nonetheless restores many people to their prior level of functioning and inspires others to find new meaning in their lives. For this reason, cognitive adaptation occupies a special place in the roster of human capabilities" (p. 1171).
