1988 DRUG USE FORECASTING ANNUAL REPORT

**Drugs and Crime  
in America**

# Drug Use Forecasting

## From the Director

The President's National Drug Control Strategy emphasizes the importance of accurate and timely information about the dimensions of drug abuse in America, and for good reason: timely and reliable reference points are essential for targeting strategies and charting progress against illicit drugs.

This report on the Drug Use Forecasting (DUF) program of the National Institute of Justice describes one of the newest Federal research efforts to clarify the nature and extent of drug abuse. DUF, along with the Household and High School Senior Surveys and the Drug Abuse Warning Network (DAWN) of the National Institute on Drug Abuse, serve as a continuous tracking system for the often shifting landscape of the illicit drug trade in the United States.

Since it was launched by the National Institute of Justice in 1987, DUF has been bringing into increasingly sharper focus the picture of drug abuse among a crucial segment of our population: those arrested for serious crime in our major urban areas.

DUF information is based on the objective results of anonymous urine testing of samples of arrestees in 22 cities in all parts of the country, augmented by information from voluntary interviews.

Each quarter, the National Institute of Justice analyzes this information to help participating cities as well as other State and local policymakers monitor drug use trends and probe what works and what doesn't in drug prevention, education, and enforcement. DUF is also a breakthrough as a research tool, providing social scientists with an accurate and reliable measure of drug use among criminal suspects.

As this report shows, there is no single national drug problem; there are many, and each requires individualized strategies. Drugs of choice may vary region by region, necessitating not only different prevention and enforcement approaches, but different treatment modalities. Cocaine use, for example, is much higher in the Northeast than in the

Midwest, South, and West. Amphetamine use is virtually confined to the West.

DUF interviews in 1988 provided useful information about other aspects of arrestees' lives that can help us modify or reinforce tactics for attacking drug use where it is most entrenched and dangerous. Interviews with women who were arrested, for example, reveal that an exceptionally high proportion are injecting cocaine. This finding raises the specter of additional serious problems—addicted infants, HIV-positive infants, and child neglect.

The school dropout rate among arrestees is high. The majority of the arrestees in 20 of the DUF cities had not completed the 12th grade. The policy implications are clear: treatment planners need to take educational level into account. Equally important, we need to keep in mind that to have a complete picture of drug abuse, surveys of students need to be augmented with information on those who are no longer in school.

Even as NIJ distills more policy insights from the Drug Use Forecasting research, efforts are underway to enlarge the program's contribution. An advisory panel of distinguished researchers (listed below) met recently to help guide NIJ in refining the collection and analysis of data and in charting research that will give us the knowledge needed to keep anti-drug strategies on target.

## Overview

In 1987, the National Institute of Justice began the Drug Use Forecasting (DUF) program in New York City. By 1988, 20 cities had entered the program. DUF is designed to provide each city with estimates of drug use among arrestees and information for detecting changes in drug use trends. The DUF program provides the country with the first objective measure of recent drug use in this deviant segment of the population. The information can be used to plan the allocation of law enforcement, treatment, and prevention resources, as well as to gain an indication of the impact of local drug use reduction efforts.

## Method

DUF data are collected in central booking facilities throughout the United States. For approximately 14 consecutive evenings each quarter, trained local staff obtain voluntary and anonymous urine specimens and interviews from a new sample of arrestees. In each site, approximately 225 males are sampled. One hundred female arrestees are also interviewed in some of the sites (see table on the following page). Sample sizes for the year 1988 differed from city to city because cities joined the DUF program at various times throughout the year.

Response rates were consistently high, with over 90 percent of the arrestees approached agreeing to be interviewed. More than 80 percent of the persons interviewed provided a urine specimen.

To obtain samples with a sufficient distribution of arrest charges, DUF interviewers limited the number of male arrestees in each sample who were charged with the sale or possession of

## Drug Use Forecasting (continued)

drugs. Because this group of arrestees is undersampled and because such persons were most likely to be using drugs at time of arrest, DUF statistics are minimum estimates of drug use in the male arrestee population. All female arrestees, regardless of charge, are selected for inclusion in the DUF sample because of the small number of female arrestees available.

Urine specimens are analyzed by EMIT™ for 10 drugs: cocaine, opiates, marijuana, PCP, methadone, benzodiazepine (Valium), methaqualone, propoxyphene (Darvon), barbiturates, and amphetamines. Positive results for amphetamines are confirmed by gas chromatography to eliminate positives that may be caused by over-the-counter drugs. For most drugs, the urine test detects use in the prior 2 to 3 days. Exceptions are marijuana and PCP, which can sometimes be detected several weeks after use.

### 1988 Results

In 1988, 20 cities collected data on male arrestees. In 14 of those cities, female arrestees were also interviewed. Results from each quarter of data collection were aggregated by city. Pages 4 to 8 show the percentage of arrestees testing positive for any drug, multiple drugs, marijuana, cocaine, and opiates (heroin). The remaining sections of the report describe injection behavior, geographical differences in drug use, history of drug use, age of onset of drug use, demographics, and charge distribution of the sample.

### Overall Drug Use

The percentage of males testing positive for any drug at time of arrest ranged from 54 percent (Indianapolis and Kansas City) to 83 percent (New York). In 9 of the 20 cities, 70 percent or more of the males tested positive for at least 1 of the 10 drugs. The range for female arrestees was from 44 percent (St. Louis) to 81 percent (Detroit). In 8 of the 14 cities that tested female arrestees, more than 70 percent were positive.

The relationship of age to drug use differed little from city to city. In general, more than half of all males tested positive, regardless of age. Drug use was also found in female arrestees of all ages. Drug use was prevalent in male and female arrestees of all races.

**Multiple Drug Use.** Males testing positive for more than one drug at the time of arrest ranged from a low of 12 percent in Indianapolis to a high of 55 percent in San Diego. Female arrestees in Chicago were most likely to test positive for multiple drugs (47 percent), while females in Kansas City were least likely to test positive (18 percent). Multiple drug use was found in all age categories and ethnic groups.

**Marijuana.** The percentage of male arrestees testing positive for marijuana ranged from 17 percent in St. Louis to 50 percent in Chicago and Portland. About one-quarter to one-third of all male arrestees tested positive for marijuana in 1988. Male arrestees were more likely to test positive for marijuana than were their female counterparts. In 12 of the 14 cities, the percentage of males testing positive for marijuana was at least 5 percentage points higher than that found for females.

**Cocaine.** For the majority of both male and female arrestees, cocaine was the most prevalent drug found. The range of cocaine positives among males was from 15 percent in Indianapolis to 74 percent in New York. In most cities, cocaine was found in 40 percent or more of male arrestees. The lowest percentage of female arrestees testing positive for cocaine was found in San Antonio (26 percent), and the highest percentage was found in New York (75 percent). In some cities, more females than males tested positive for cocaine.

**Opiates (Heroin).** The urine test results for opiates, while low, are reported because of the well-established link between heroin use and crime. Opiate use in male arrestees ranged from a low

of 1 percent in Miami and Omaha to a high of 24 percent in New York. Female arrestees were as likely to test positive for opiates as were male arrestees.

# Injection in Arrestees and CDC Estimates of AIDS

Data from the DUF program show a high incidence of recent drug use among arrestees in the largest U.S. cities. Moreover, information from DUF interviews indicates that a substantial number of drug users report having injected drugs. The table at right shows injection rates from male and female arrestees in DUF cities. For example, in New York City, 24 percent of the male and 30 percent of the female arrestees interviewed reported ever having injected drugs. In most DUF cities, as in New York City, female arrestees were more likely to admit intravenous (IV) drug use.

IV drug users predominate as the source of heterosexual and perinatal transmission of human immunodeficiency virus (HIV)—the virus that causes AIDS. The most dramatic increases in AIDS in the past few years have been among IV drug users, their sexual partners, and their children. Among DUF cities, the percent of AIDS cases attributed to IV drug use ranges from 6 percent in Indianapolis males to 62 percent in New York City females. IV drug users are at particularly high risk of contracting and transmitting HIV due to their needle-sharing behavior.

Despite the high risk of contracting HIV associated with needle sharing, large numbers of drug injectors continue to share needles. Of male and female arrestees in New York City who reported ever having injected drugs, 29 percent and 17 percent, respectively, reported that they currently share needles. While many male and female needle sharers indicated that they had changed their needle-sharing behavior as a result of the AIDS epidemic, misconceptions about AIDS were common. Some of the changes drug users reported making, such as "I only share with friends," and "I don't share with unclean people," are ineffective barriers against HIV transmission. These data overwhelmingly indicate the necessity for AIDS education, prevention, and outreach efforts among the IV drug using population.

## Regional Differences in Drug Use: Male Arrestees

Previous DUF reports have shown wide variation in patterns and types of drug use in the 20 cities currently testing male arrestees. The cities were placed in one of four regions—Northeast, Midwest, South, and West—as defined by the U.S. Bureau of Census (see map).<sup>1</sup> Washington, D.C., urine results, obtained from D.C. Pretrial Services, are included in drug use analysis. Data from Washington, D.C., are not included in analysis of demographics. Grouping these cities into regions reveals distinct regional

differences in drug use among arrestees and in demographic characteristics of arrestees.

In 1988, arrestees in the Northeast had the highest rate of drug use: 82 percent tested positive for one or more drugs, including marijuana (omitting Washington, D.C., which does not test for marijuana). The second highest region was the West (74 percent) followed by the South and the Midwest. In the Northeast, more arrestees also tested positive for multiple drugs (29 percent), excluding marijuana,

with the West having the second highest rate of multiple drug use (22 percent).

Although cities in a region may deviate somewhat from the regional average<sup>2</sup>, regional comparisons can be useful in examining patterns of drug distribution and the factors that may be related to regional differences in drug use. Regional statistics may be especially useful for those jurisdictions that are not DUF sites but need current information about possible drug use patterns in their area.

Percent Positive for Any Drug by Region

West – 74% (n=3,912)	Midwest – 63% (n=2,204)	South – 68% (n=2,969)	Northeast – 82% (n=1,377)
----------------------	-------------------------	-----------------------	---------------------------

<sup>1</sup>The Census Bureau places Washington, D.C., in the South, but it is included here in the Northeast because of its similarity to other cities of that region. Omaha testing began late in 1988 and is not included in the tables.

<sup>2</sup>The DUF cities in each region are thought to be fairly representative of drug use patterns in other large cities in the region, but the regional data may not explicitly describe specific locales. In the tables that follow, a simple arithmetic average of all cases was used for the Northeast and West regions. In the South and Midwest, where city sample sizes were quite variable, averages were computed separately for each city and then an overall regional average was computed.

## Regional Differences in Drug Use (continued)

### Types of Drugs

Regional differences are most evident in the use of specific drugs. The highest rates of cocaine use—almost 70 percent—were found in the Northeast. Cocaine use was much lower, and surprisingly similar, in the Midwest, South, and West (43 to 48 percent). Opiate use is much more prevalent in the Northeast and West than elsewhere. Only one city in the South deviated from this pattern: 18 percent of arrestees in San Antonio tested positive for opiates in 1988.

Amphetamine use is virtually confined to the West (15 percent), with the lone exception of Dallas where amphetamines were found in 6 percent of arrestees. PCP use is generally below 5 percent in all cities; the exceptions are Washington, D.C. (31 percent), Chicago (14 percent), and St. Louis (9 percent).

### Demographic Characteristics

Demographic characteristics of arrestees also vary across the four regions. Unemployment among arrestees (those on welfare or employed sporadically, but not part-time) is highest in the Northeast at 55 percent. Elsewhere, about 40 percent of arrestees are unemployed.

In the Northeast arrestees are 88 percent nonwhite (including Hispanic and other minorities), whereas nonwhite arrestees in the other regions are between 71 and 77 percent of the total. Hispanics constitute about one-quarter of the arrestees in the West (28 percent) and Northeast (24 percent), but only 5 percent in the Midwest and 15 percent in the South. School dropout rates among arrestees are highest for the Midwest (61 percent), followed by the Northeast (58 percent), the South (54 percent), and the West (49 percent).

Arrestees in the Northeast and Midwest are roughly a year younger (about 28 years) than in the South and West (about 29 years). Reported age at first use of marijuana (15–16 years) and cocaine (20–22 years) appears slightly younger in the Northeast and West than in the South and Midwest (data not shown).

# Female Arrestees: Drug Use by Self-Report and Urinalysis\*

During the DUF interviews, arrestees were asked about their recent drug use. Recent use is defined as drug use 24 to 48 hours before arrest. Urinalysis can detect most drugs within this time. The tables below compare estimates of recent marijuana, cocaine (including crack), and heroin use based on self-reports and estimates based on urinalysis.

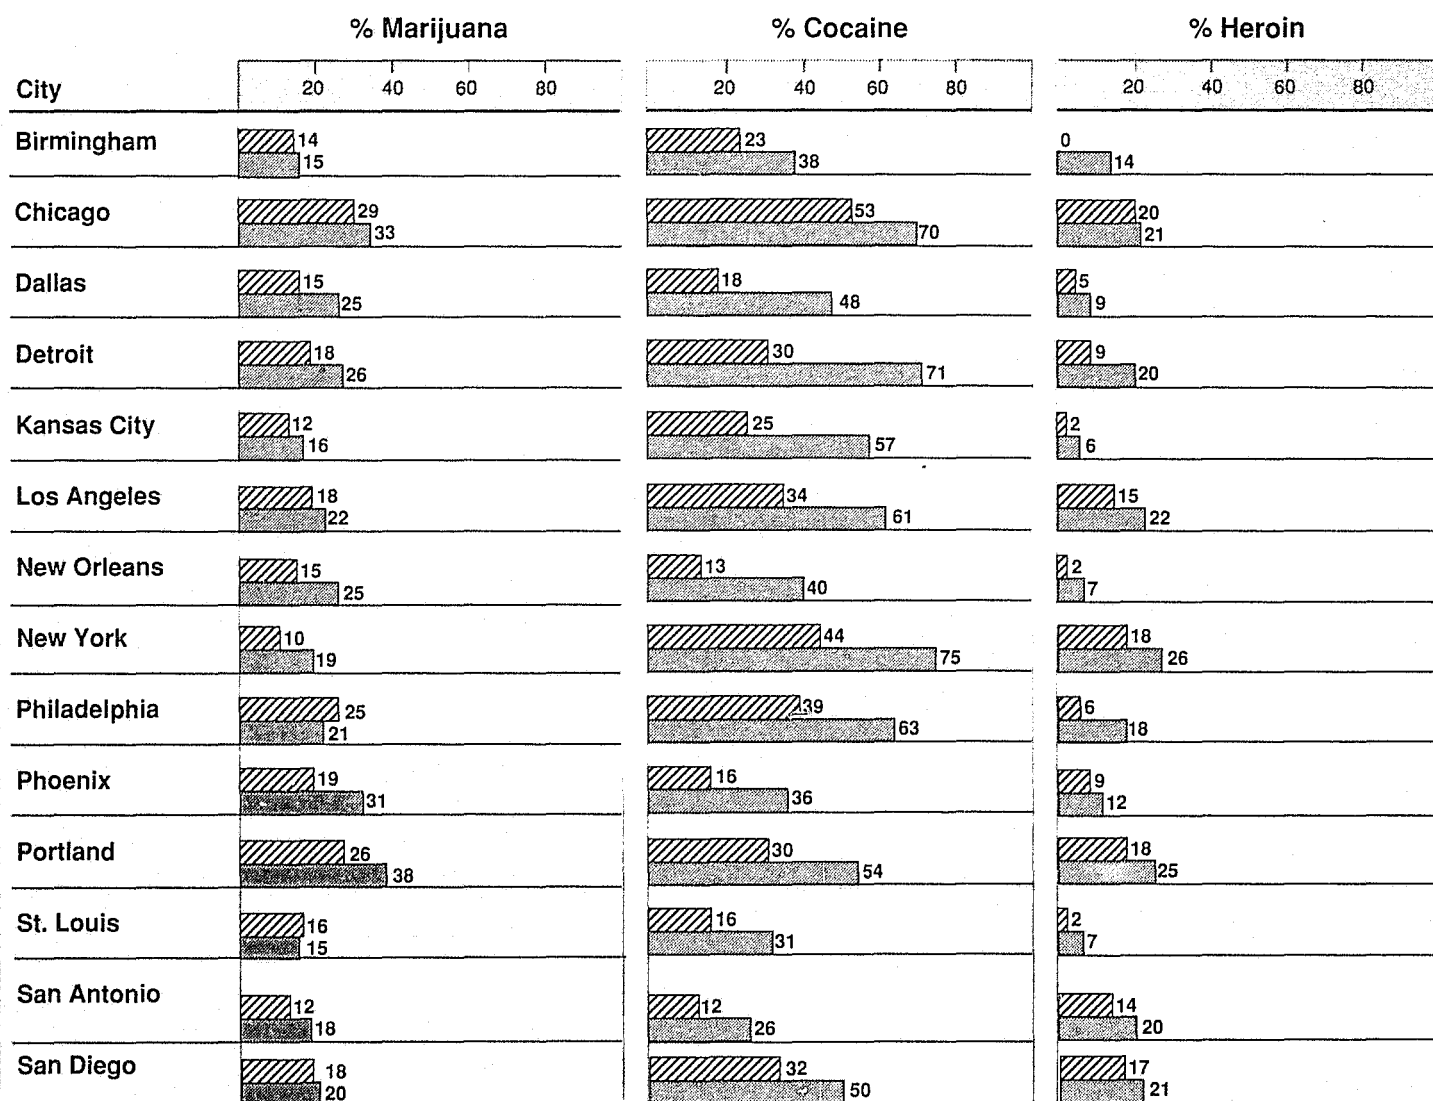

In Houston, only 15 percent of male arrestees self-reported recent use of marijuana compared to 43 percent testing positive by urinalysis (see chart to the

left). In Ft. Lauderdale, New Orleans, and San Antonio, male arrestees underreported recent marijuana use by 50 percent. This finding may occur because marijuana can be detected by urinalysis up to several weeks after use. In other sites, however, self-reports of marijuana use came much closer to reflecting actual use. Overall, female arrestees were more likely to self-report recent use of marijuana.

For male arrestees, estimates of cocaine use based on urine tests were about twice as high as those based on self-reports.

For example, less than 20 percent of the males self-reported recent use of cocaine in Detroit and New Orleans; urinalysis results show that more than 50 percent of them tested positive for cocaine at time of arrest. Female arrestees also underreported recent cocaine use, but less so than males.

Arrestees' self reports of heroin use more closely approximated urinalysis findings. The exception was in Birmingham where females reported no recent heroin use, but 14 percent tested positive.

% positive by urinalysis

# Male Arrestees: Self-Reported Alcohol and Marijuana Use\*

## Drug Use History

Arrestees were asked to report their history of drug use. The following information was obtained for each drug used: the user's age of onset, frequency of use, dependency, use in the last month, and use in the last 24 to 48 hours. Because arrestees underreport illicit drug use, the statistics in the following tables should be considered

minimal estimates of drug-related behavior in this population.

## Alcohol

In every city except Miami, more than 92 percent of the male arrestees had used alcohol. In Miami, 82 percent of arrestees reported having tried alcohol. The median age of first use of alcohol ranged from 14 to 16 years. Between 6 percent (Miami

and New Orleans) and 30 percent (Indianapolis) of the users reported feeling dependent on alcohol at some time in their lives. In all cities, 55 percent or more of the male arrestees had used alcohol in the last 30 days. When asked about alcohol use in the last 24 to 48 hours, approximately 50 percent of the arrestees reported recent use. Indianapolis and Omaha arrestees reported the most recent use of alcohol,

\*Data based on voluntary self-reports, January through December 1988

## Female Arrestees: Self-Reported Alcohol and Marijuana Use\*

71 and 72 percent, respectively. Arrestees in these two sites were also more likely to report dependence on alcohol—30 percent for Indianapolis (the highest percent of self-reported dependency) and 23 percent for Omaha.

Female arrestees were also likely to report having tried alcohol. Greater than 86 percent of all females admitted alcohol use. The median age of onset for alcohol use among female arrestees was 15 to 17 years, approximately 1 year older than males. Between 4 percent (New Orleans) and 23 percent (Detroit) of the users reported ever being dependent on alcohol. Forty-eight percent or more of the female arrestees reported using alcohol in the last month,

and greater than 25 percent reported alcohol use in the last 24 to 48 hours.

### Marijuana

More than 66 percent of all male arrestees had used marijuana. The highest reported use was found in Birmingham (92 percent); the lowest reported use was found in Houston (67 percent). The range of onset of marijuana use was 15 to 17 years. The majority of the arrestees reported a median age of onset of 15, and only one city, Houston, reported onset of marijuana use at age 17.

Arrestees in Indianapolis were most likely to report dependence on marijuana—22 percent of the users. In the remaining cities, less than 19 percent of the users

reported marijuana dependency. More than 18 percent of male arrestees reported using marijuana during the last 30 days. The range of recent marijuana use (use in the last 24 to 48 hours) was from 15 percent in Houston to 36 percent in Portland.

More than 60 percent of the female arrestees in each city reported having tried marijuana. Age of onset for marijuana use was similar to the age of onset reported by male arrestees: 15 to 17 years. Nineteen percent or more reported marijuana use in the last 30 days. Females were less likely than males to report marijuana use in the last 24 to 48 hours—less than 30 percent.

# Male Arrestees: Self-Reported Cocaine and Crack Use\*

## Cocaine

Approximately 40 percent or more of the male arrestees reported ever using cocaine. Arrestees in Houston reported the least use—28 percent. The median age of onset of cocaine use was 14 to 22 years, with the majority of the arrestees reporting onset at 20 years or older. In New York and Philadelphia, almost half (47 percent) of the cocaine

using arrestees reported having been dependent on it at some time. The lowest percent of self-reported cocaine dependence was found in Ft. Lauderdale arrestees—12 percent. Arrestees in Houston reported the lowest use in the last month (10 percent), and arrestees in Indianapolis reported the lowest use in the last 24 to 48 hours (7 percent). More than 30 percent of the arrestees in New

York and Philadelphia reported using cocaine during the last 2 days.

More than 35 percent of female arrestees reported ever having used cocaine. The median age of onset was 19 to 22 years, with arrestees in only two sites reporting 19 years as the initial age of use. In all but two cities, New York and San Antonio, more than

\*\*\* Less than 1%

## Female Arrestees: Self-Reported Cocaine and Crack Use\*

22 percent of those arrestees who reported ever using cocaine also reported dependence on it. Between 16 and 62 percent of the females reported cocaine use in the last month. Fifty-three percent of the female arrestees in Chicago reported cocaine use in the last 2 days.

### Crack

Self-reported crack use among male arrestees ranged from 4 percent in Chicago to 43 percent in New York. The

relatively recent emergence of crack may explain the wide range of self-reported crack use. For this reason, the median age of onset of crack was not reported. Excluding St. Louis, where only 7 percent of users reported dependence on crack, between 17 and 66 percent of crack users reported ever being dependent on the drug. Arrestees in New York were most likely to report using the drug in the last 30 days (33 percent), and in the past 24 to 48 hours (29 percent).

Only 3 percent of the female arrestees in New Orleans had ever used crack. Detroit had the highest reported use at 68 percent. With the exception of Phoenix, 22 percent or more of the crack users reported feeling dependent on crack. In Phoenix, only 13 percent of the crack users reported ever being dependent. Females arrestees in Detroit reported the most crack use in the last month (47 percent) and, with New York, reported the highest use of crack in the last 24 to 48 hours (27 percent).

# Male and Female Arrestees: Self-Reported Heroin Use\*

## Heroin

Male arrestees in New York reported the highest percent of lifetime use of heroin—33 percent. Arrestees in Houston were least likely to have used heroin—7 percent. Onset of heroin use ranged from 17 to 23 years. More than 20 percent of heroin users reported dependence on heroin with the exception of arrestees in Ft. Lauderdale, where only 12 percent reported ever being dependent. Seventy-eight percent of heroin users in New York reported dependence. Self-reported recent use of heroin was low in all cities, less than 21 percent for the last month and less than 18 percent for the last 24 to 48 hours.

Among female arrestees, self-reported use of heroin ranged from 9 percent in Kansas City and New Orleans to 46 percent in Chicago. The median age of onset of heroin use was 18 to 21 years. In 10 of the 14 cities, more than 50 percent of the female users reported dependence on heroin. Twenty-five percent or less reported heroin use in the last month or in the last 2 days.

# School Dropout Among Arrestees

In 1988, DUF collected information from arrestees in 20 cities throughout the United States. In addition to drug use histories, arrestees were asked about other aspects of their lives. For example, arrestees were asked to report their highest level of education. An analysis of these data indicated that the majority of arrestees in the 20 cities had not finished the 12th grade. The percentage of male arrestees who had not completed high school ranged from 32 percent in Fort Lauderdale to 67 percent in San Antonio (data not shown). Female

arrestees in San Antonio were most likely to have dropped out of school (59 percent). The lowest rate of high school dropout among female arrestees was found in Los Angeles (44 percent).

The table below shows the dropout rates according to ethnicity. The rate of dropout among Hispanic arrestees was especially high: 60 percent or more of Hispanics dropped out of school before completing 12th grade. The term Hispanic in this context refers to a number of different ethnicities, e.g., Mexicans in San Antonio, Cubans and Puerto Ricans in New York.

The dropout rates in arrestees underscored the limitations of surveys of drug use in senior high school students. With greater than one-third of all arrestees and more than 60 percent of Hispanic arrestees dropping out of school before 12th grade, it is evident that this highly deviant and drug abusing portion of the population is omitted from high school surveys. A more representative picture of national drug use can be obtained by integrating epidemiologic information from diverse segments of the total population.

## Age and Race of Male Arrestees\*

DUF collects a variety of demographic information about the arrestees who are interviewed, including age, race, employment, and marital status. Knowledge of this population could be useful for planning treatment programs, outreach efforts, and other social programs. The next several pages compare and contrast demographic characteristics among male and female arrestees.

### Age

Roughly half of all male and female arrestees were 21 to 30 years old. Although some characteristics of arrestees vary substantially by city, the age of male and female arrestees showed little variation across cities. The average age of males and females (not shown) was virtually identical in each city.

Some differences did exist when comparing the age distribution of male arrestees to the age distribution of female arrestees. The tables show that there are more males than females in the youngest age category (15 to 20 years). Females were more likely than males to be 21 to 30 years old. However, the arithmetic average age for male and female arrestees interviewed for the DUF project was the same, about

City	Age (In Percent)					Race (In Percent)			
	15-20	21-25	26-30	31-35	36+	Black	White	Hispanic	Other
Birmingham	10	30	23	19	18	70	30	0	0

## Age and Race of Female Arrestees\*

28.7 years. Thus, although many perceive the age of a typical arrestee to be about 20 years old, these data show that persons in their late 20's and 30's were common in samples of arrestees.

### Race

The race distribution of male and female arrestees in the DUF data showed a much different picture. As expected, variation was greater among cities than between the sexes. Blacks were the largest racial group for both male and female arrestees in most cities. In Chicago, Cleveland, Detroit, New Orleans, Philadelphia, and St. Louis, more than 70 percent of male arrestees were black. These cities (except

Cleveland, which did not test females), as well as Kansas City, had high percentages of black female arrestees.

Hispanic arrestees predominated in San Antonio for both male and female arrestees (over 50 percent of the total). Other cities with large representations of Hispanic arrestees, for both males and females, included Los Angeles, New York, Phoenix, and San Diego. Also, 25 percent of male arrestees in Miami, which did not test females in 1988, were Hispanic.

White arrestees were the largest racial group in Phoenix, Portland, and San Diego in the female and male DUF samples. Ft. Lauderdale and Omaha (which did not

test females in 1988) also had large proportions of white male arrestees. When comparing the race distribution of male and female arrestees city by city and overall, females in many DUF sites were more likely to be white than male arrestees. For example, in Dallas 46 percent of female arrestees were white, whereas only 30 percent of male arrestees were white. Similar differences in the percentage of white females and males were also found in Detroit and San Diego.

Other racial groups accounted for at least 5 percent of female arrestees in Phoenix and Portland, and male arrestees in Omaha.

# Employment and Marital Status of Male Arrestees\*

## Employment

Less than 50 percent of both male and female arrestees in most cities were working full-time, according to data collected by DUF in 1988. In many cities, only 20 to 40 percent of arrestees were fully employed. However, there

was considerable variation across cities in the extent of employment among arrestees. Full- or part-time employment for male arrestees was highest in Birmingham, Ft. Lauderdale, Indianapolis, Miami, Omaha, and Phoenix (more than 70 percent). The unemployment situation was worst for male arrestees in New York

(57 percent), followed by Chicago with 44 percent, and Portland with 43 percent.

The employment status of female arrestees was somewhat different than that of males. Unemployment was actually more severe for female

# 

arrestees than for male arrestees. More than 50 percent of female arrestees in 12 of 14 cities were unemployed—a much higher rate of unemployment than the male arrestees reported. However, many of these women may not have been seeking employment. Full- or part-time employment for female arrestees was highest in Birmingham, Dallas, Kansas City, and St. Louis (over 40 percent).

### 

Male and female arrestees in the DUF cities were predominantly single (never married). A rather sizable group of male and female arrestees, given their young age, were separated, divorced, or widowed: more than 20 percent of female arrestees in all but three cities and at least 15 percent of males in most cities. Female

and male arrestees who are married generally comprise less than 20 percent of the total.

In general, the demographic differences between male and female arrestees interviewed by the DUF project were surprisingly small. The typical arrestee was about 29 years old, nonwhite, unemployed, and never married.
