Introduction

Over the centuries people have sought to understand the forces which cause some members of society to commit criminal acts. Theories of criminality have evolved as new ideas have coursed through society, some attaining preeminence for a time before being subsumed under a new wave of thought. Each of these, such as the classical school, which held free will paramount, and the positivist school, which held that criminal behavior was biologically determined, has some contribution to make toward the study of crime; yet none of them, when taken in isolation, adequately explains the phenomenon of crime.

Early theories focused on biological determinants, holding that criminal behavior was inherited or was a manifestation of an evolutionary throwback, or atavism. As the classical school gave way to positivism, so positivism gradually eroded as the dominant school of criminology under the onslaught of psychology and sociology.

In recent years the focus has been on sociological and psychological correlates of crime—poverty, unemployment, discrimination, poor family life, and early child-hood deprivation are some of the factors that have been associated with criminality.

Although the literature of the social sciences makes an important contribution to our understanding of criminality, it does not hold all the answers. Current research has pointed to some possible determinants of criminal behavior in the organism itself. It is appropriate to examine some of the work of nutritionists, doctors, biologists and others from the physical sciences as we seek a new, holistic synthesis concerning criminality.

Cesare Lombroso's *l'uomo delinquente* (1876) is generally considered the beginning of the study of biological factors on criminality, although physiognomy, the study of facial features, and phrenology, the study of external cranial structure, had been known as early as the time of Aristotle and had evolved into recognized disciplines by the time Lavater's *Physiognomical Fragments* (1775) was published. The biological model of criminality focuses on biological, somatological, and anthropological factors as they influence criminal behavior. This orientation posits the criminal as biologically different from other humans. Lombroso's "atavistic criminal," Goring's "criminal diathesis," and Sheldon's somatotypes are examples, although now largely discredited.

This bibliography is a compilation of recent literature in the NCJRS collection on biological influences on criminal behavior. The earliest citations date from 1955, shortly before the surge of growth of criminology during the sixties. It does not include the classical works, such as those of Lombroso, Lavater, Ferri, Goddard, Sheldon, or Hooten. Nor are the earlier works of modern pioneers, such as K. O. Christiansen or S. H. Shah, included. The rich European literature concerning biological influences and criminal behavior is also somewhat underrepresented.

This bibliography is not intended to revive the nature-nurture controversy nor to advocate biological influences at the expense of social factors. Rather, these selections may be viewed as representative of a biological approach to the study of criminality.

Many of the factors which may contribute to the development of criminal behavior, but which rarely, if ever, appear in the social science literature will be reviewed here. The documents have, as their central focus, a concern with various biological phenomena hypothesized as being associated with criminal behavior. Glaser (1974) provided an apt explanation of how biological will be used in the present context: "By biological we refer to a broad range of processes and conditions that typically are considered as belonging to or 'characteristic of' the organism, rather than its 'present' environment." Whereas much of the criminological literature describes the various influences of the social environment on the opportunity for and disposition toward crime, this bibliography provides references to biological, genetic, and medical studies of the causes of criminal behavior. A brief overview of the types of material cited follows.

The influence of various epileptic disorders, as they relate to criminal behavior. is presented, as are studies of electroencephalogram abnormalities. Learning disabilities, minimal brain dysfunctions, and visual problems among delinquents have also recently been examined. Neurological abnormalities, discreters of the brain or disturbances in its chemical balance, such as hyperkinesis, may influence criminality, Genetic research concerning chromosomal abnormalities, such as 47, XXY (Klinefelter's syndrome) producing extreme tallness and distinct EEG pattern, examines the possibility of inheritable aspects of criminality. The work of K. O. Christiansen and his cohort studies of Danish twins is a prime example of the research on genetic influences. Disorders in the endocrine system, the system of glands regulating internal functions, have been associated with criminal behavior, often with regard to sexual offenders. Limbic system disorders, affected by sugar diabetes and hypoglycemia (low blood sugar), have been associated with violent, sometimes criminal, behavior. Psychophysiological indices related to emotional response may also play a role. Galvanic skin response may be indicative of the aptitude for learning inhibiting behavior; biochemical balances, such as levels of adrenaline and noradrenaline, are associated with aggression. Some of the literature from psychopathy is relevant in this regard.

Over a decade ago former President Lyndon Johnson's Commission on Law Enforcement and the Administration of Justice found the American criminal justice system a fragmented hodgepodge of agencies pursuing uncoordinated strategies to control crime. That Commission recommended a systems approach to the problem of crime control. By recognizing that the activities of one component of the system can impact on another—increased arrests by police yield both heavier court dockets and more people being processed into the correctional system—we have improved our reactions to crime. However a holistic approach is also necessary to understand the variety of factors which may cause or predispose an individual to commit criminal acts. Both social and biological forces shape the individual; it is only by understanding the totality of influences on the individual that we may begin to construct proactive measures to render our responses more effective.
