NLETS NETWORK COST REDUCTIONS

3 October 1974

B. Goldstein

Introduction:

The goal of this study was to investigate techniques for cost savings for the present NLETS Network configuration. The use of line multiplexing was the primary item considered. Purchase of modems, although a potential saving, does not compare with possible savings through line multiplexing. Multidropping is another technique for large cost savings but its use is not desired by NLETS.

Methods of Analysis

Both Frequency Division Multiplexing (FDM) and Time Division Multiplexing (TDM) techniques are used. Cases 1 through 6 employ the former method, while Cases 7 through 12 employ the latter and Case 13 illustrates TDM use with asynchronous terminals only. A summary of costs is given in Table 1. Also reference maps are included that permit the reader to identify the states involved in each candidate case. Popular manufacturers were used for typical costs. Unit list prices were used although quantity discounts and special governmental discounts through GSA would improve savings. Detailed costs of the candidate cases are included in Appendix A. Each case is described by first showing its multiplexed configuration and costs, next showing its non-multiplexed configuration (i.e. the present NLETS configuration) and costs and finally showing the difference between the present and proposed configuration costs, which in all cases selected results in dollar savings. Providing private line or dial backup capability to the multiplexed configuration would reduce the savings by the amounts indicated. Details given with each case allow the reader to extrapolate the technique to other cases. Costs for dial backup configurations are given in Appendix B. Both manual and automatic dial backup methods are discussed. Dial backup offers a low cost alternative to cover private line or equipment failures in multiplexed networks.

65876

Conclusions and Comments

1. General

Potential for dollar savings lies primarily in reducing network line mileage costs. All multiplexing techniques applied in the Eastern U.S. afford dramatic savings while multiplexing closer to Phoenix rapidly reaches a point of diminishing returns. Some additional savings could be made by buying rather than leasing modems. However by comparison the proportion of savings is small because line costs constitute close to 60% of NLETS actual costs while modems account for only 6% of the total.

2. FDM - asynchronous only - Cases 1 through 6

Because NLETS asynchronous terminals will eventually upgrade to become synchronous terminals they will each drop off of the FDM channel, reducing its efficiency. Consequently investment in FDM equipment is not recommended.

3. TDM - asynchronous only - Case 13

The same comment as made above would hold true if the TDM equipment were capable only of handling asynchronous inputs. However the TDM multiplex equipment used in Case 13 is capable of handling up to 3 - 2400 b/s synchronous lines plus a number of asynchronous inputs. The modem shown would then require upgrading to match the new transmission rate over the same voice grade line.

4. TDM - synchronous only - Cases 7 through 9

This appears to be a reasonably cost effective way of multiplexing a small number (4) of 2400 b/s users. Leasing arrangements favorable to NLETS (1 month termination notice) by using 209A's are attractive and private firms are now in the process of revamping their lease/purchase prices to meet this competition.

5. TDM - synchronous and asynchronous - Cases 10 through 12

These are easily reconfigured if terminals change from 150 b/s to 2400 bps or 2400 to 4800, etc.

Savings are significant when large numbers of geographically close terminals are served.

Purchase of multiplexer with lease of Bell 209 modems is an attractive option.

Bell may provide leased service using Timeplex equipment in the near future.

Appendix B

Dial Backup Details

1.0 General

In cases where failure of private line (PL) connection(s) in a network would cause serious problems, the direct distance dial (DDD) network is sometimes used for backup. Its main advantage is low cost. While the DDD network is in backup mode the private line circuit would be repaired. The main disadvantage of the DDD network is that satisfactory data transmission above 4800 b/s is generally not achieved.

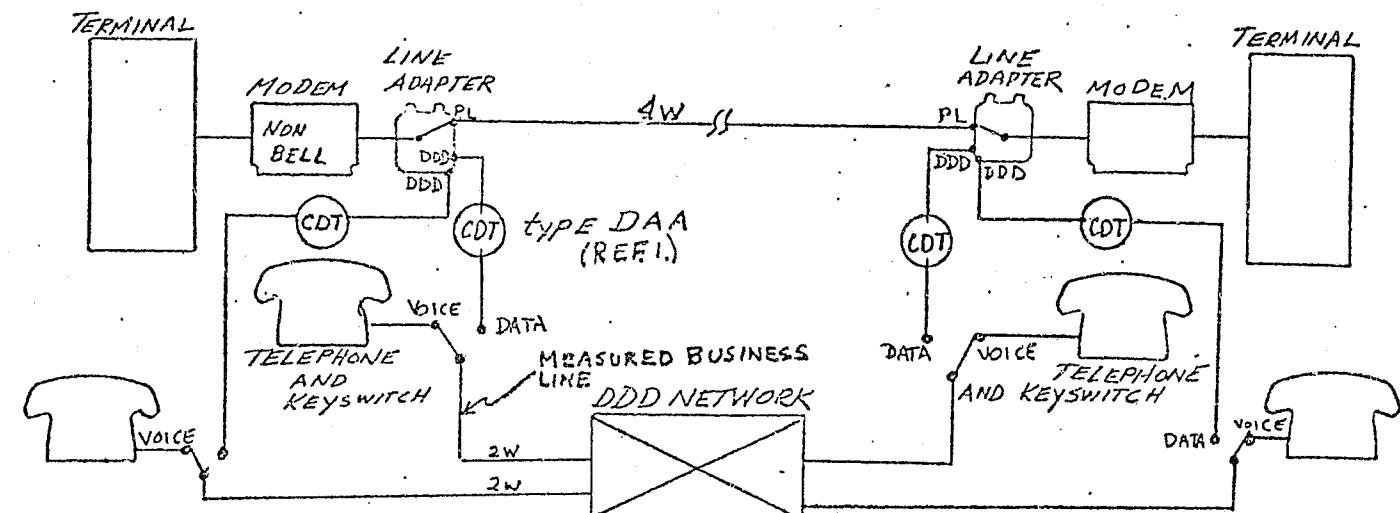

In the case of data transmission using non-Bell Telephone Company modems there is a legal requirement for protecting the DDD network. This is accomplished by connecting a Data Access Arrangement (DAA) unit between the modem and DDD connection. DAA's are not needed when the Telephone Company interfaces their own modems. Where non-Bell Modems are used, line adapters are also required. These can be built into the modem but are usually separate units. The line adapter function may be built into other interface equipment such as the Linebacker described in paragraph 2.2. The line adapter contains the PL/DDD connection switch as well as impedance and power matching circuitry.

2.0 Dial Backup Methods

To back up private line 4 wire duplex transmission, two 2 wire dialup links must be established.

2.1 Manual Method

The manual method is common. An operator will dial-up separate transmit and receive circuits. He will talk to the operator at the other end and coordinate to insure that their modems are switched from PL to DDD connection. They will then coordinate switching both telephones from the voice or talk mode to the data mode. Full duplex transmission may then proceed over the DDD network. When the private lines are repaired the operators at both ends must "hang up," go back to voice mode, and switch the line connection from DDD to PL for normal operation. Notice that while in the dial backup mode, the operators cannot call each other over the send or receive circuits, so that another means of communication or pre-arrangement for switching back to PL operation is needed.

4 wire operation requires 4 wire PL or 2 telephones with key switches at each end.

Figure 1a - Manual Method - Non- Bell

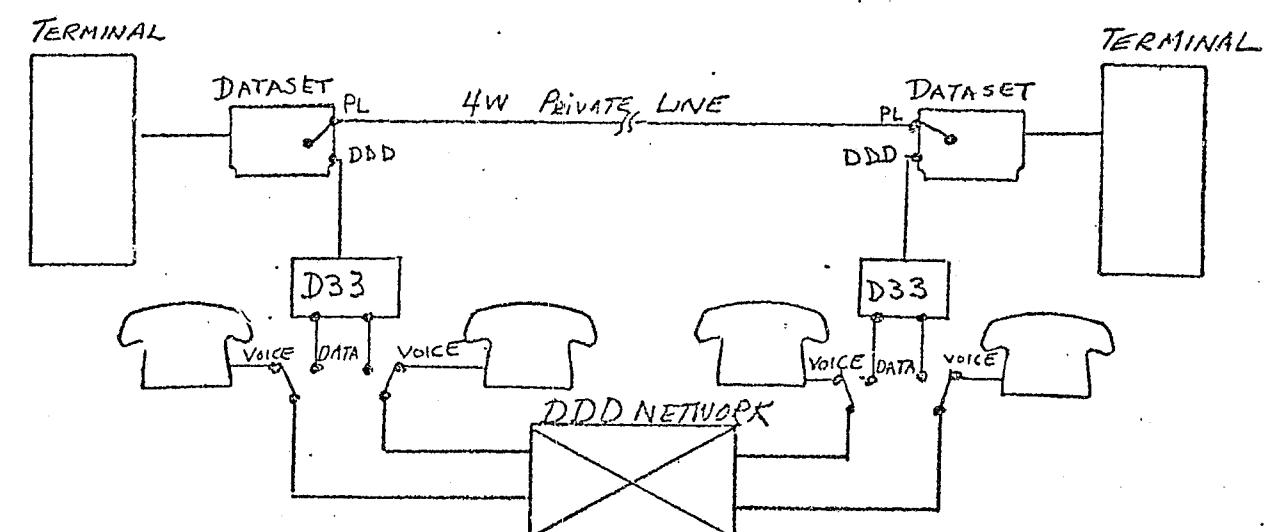

Fig. 1b - Manual Method - Bell

2.2 Automatic Method

It is also possible to accomplish the dial backup automatically. See Fig. 2. This can be done with commercially available (non-Bell) equipment like Timeplex Linebacker (Ref. 3) interfacing to the DDD network via two automatic (CBS type) DAA's (Ref. 2). Unattended operation is accomplished as follows: Linebacker A (Master) monitors the 4 wire private line performance by way of a tone loop. If the PL performance is unsatisfactory a complex bi-directional auto call-auto answer protocol with two different tones proceeds. If satisfactorily effected, both linebackers will switch the DDD connections to the modem in place of those of the PL. Dual tones and tone timing provide protection against wrong numbers. In addition the condition of the PL is continuously monitored and switchback is automatic.
