September 1985

PREFACE

The object of this publication is to supplement Crime in the United States statistics by providing Uniform Crime Reporting (UCR) data users with a variety of crime indicators and population-at-risk rates for use in their research endeavors. The report is designed to be primarily a compilation of resource materials.

Due to the structure of historical data, the report will focus on the seven Index crimes (murder, forcible rape, robbery, aggravated assault, burglary, larceny-theft, and motor vehicle theft). The document is divided into two sections. Part I consists of 75 tables pertaining to crime trends and population-at-risk rates with special emphasis on historical perspectives. Part II is labeled "The Impact of Age Composition on the Level of Crime." It is an attempt to assess the short-range impact of the recent shift in age composition on the recent decline in reported crime.

It should be noted that all data contained in this publication relates to national totals. Appendix A describes definitions, terminology, and data sources. The modes of computation for Tables 24, 25, 26, and 27 are delineated in Appendix B.

PART II

THE IMPACT OF AGE COMPOSITION
ON THE LEVEL OF CRIME

The Impact of Age Composition on the Level of Crime

After reaching a peak in 1981, the volume of Index crimes reported to the Uniform Crime Reporting (UCR) Program started to decline. During the period 1981-1983, for example, the crime volume decreased by 10 percent nationwide. One of the most frequent explanations promulgated for this decline in crime statistics is the aging of the so-called "baby boom" generation from the crime-prone ages of youth to the maturity of adulthood. While this conjecture appears plausible in many respects, attributing the movement of crime statistics solely to population composition would be shortsighted. Such a view is also too deterministic in that it ignores all endogenous factors related to criminal justice policies, resources, and their effectiveness, as well as other exogenous socio-economic influences. Therefore, the issue to address should not be whether the age structure and size of the population pyramid has any effect on the level of crime, but rather to what extent a change in the population configuration impacts the crime problem.

In this paper, the latter issue is addressed in terms of the volume of reported crimes. More specifically, the percentage of change in crime volume within two years is first divided into three components:

1. The portion arising from changes in the structure and size of the population.
2. The portion arising from changes in non-populational factors.
3. The portion arising from the interaction of the first and second components.

A method will then be suggested to bifurcate the third category into the populational and non-populational factors.

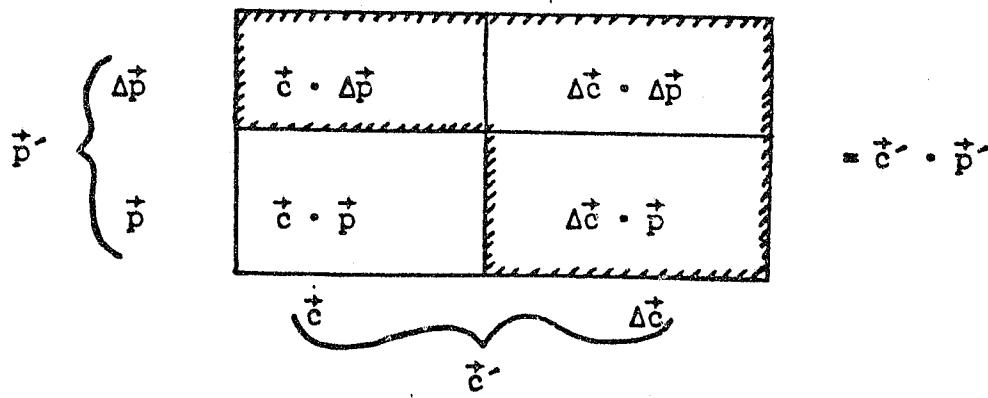

A. Decomposition of the Percentage of Change of the Crime Volume into Three Components:

Let j denote the age, $j = 0, 1, 2, \dots, 100$. For a given year, let p_j be the population consisting of those belonging to the age classification " j ". The array of population figures $\langle p_j \rangle = \langle p_0, p_1, \dots, p_{100} \rangle$ will be denoted \vec{p} . The vector \vec{p} represents the age structure and the size of the U.S. population, and is termed the population vector. Likewise, for a given year, let c_j be the age-specific crime rate for the age group j , $j = 0, 1, 2, \dots, 100$. The vector array $\langle c_0, c_1, \dots, c_{100} \rangle = \langle c_j \rangle = \vec{c}$ will be referred to as the crime rate vector. Since c_j is expressed per capita, changes of the crime rate vector \vec{c} are viewed as non-populational. It is noted that \vec{c} is not empirically known.

Let $\{\vec{c}, \vec{p}\}$ be associated with the first year and $\{\vec{c}', \vec{p}'\}$ be with the second year of comparison. Using the notation $\Delta\vec{c} = \vec{c}' - \vec{c}$ and $\Delta\vec{p} = \vec{p}' - \vec{p}$, the difference D in the volume of crimes between the two years of comparison is expressed as

$$\begin{aligned} D &= \vec{c}' \cdot \vec{p}' - \vec{c} \cdot \vec{p} \quad (\text{dot product of vectors}) \\ &= (\vec{c} + \Delta\vec{c}) \cdot (\vec{p} + \Delta\vec{p}) - \vec{c} \cdot \vec{p} \\ &= \vec{c} \cdot \Delta\vec{p} + \Delta\vec{c} \cdot \vec{p} + \Delta\vec{c} \cdot \Delta\vec{p}. \end{aligned}$$

The difference D is shaded in the diagram below indicating each of the three terms in the above expression.

The first term ($\vec{c} \cdot \Delta\vec{p}$) in the expression of D is the dot product between the crime rate vector \vec{c} (for the base year) and the populational changes $\Delta\vec{p}$. It represents the impact of the movement of the population pyramid upon the volume of crime. Therefore, ($\vec{c} \cdot \Delta\vec{p}$) is viewed as the populational component of D. The second term ($\Delta\vec{c} \cdot \vec{p}$) is the dot product of the crime rate shift $\Delta\vec{c}$ and the population vector \vec{p} (of the base year). It reflects the impact of the change in age-specific crime rates when the population and its age structure are held constant at the level of the first year. Therefore, the term ($\Delta\vec{c} \cdot \vec{p}$) indicates the influence of non-populational factors upon the volume of crime, and is referred to as the non-populational component of D. The third term ($\Delta\vec{c} \cdot \Delta\vec{p}$) denotes the combined impact of the populational and non-populational shifts. If one of the two factors ($\Delta\vec{c}$ or $\Delta\vec{p}$) is absent, the product ($\Delta\vec{c} \cdot \Delta\vec{p}$) is zero. Since it represents the interaction of two factors $\Delta\vec{c}$ and $\Delta\vec{p}$, it will be called the cross-product component of D.

Using the three components discussed in the previous paragraph, the following rates of changes are introduced:

$$x = \frac{\vec{c} \cdot \Delta\vec{p}}{V} = \text{the rate of change due to the populational factor.}$$

$$y = \frac{\Delta\vec{c} \cdot \vec{p}}{V} = \text{the rate of change due to the non-populational factor.}$$

$$z = \frac{\Delta\vec{c} \cdot \Delta\vec{p}}{V} = \text{the rate of change due to the combined effect of two factors.}$$

$$r = \frac{D}{V} = \frac{V' - V}{V} = \text{the rate of change in the volume of crime.}$$

In the above definition, V and V' denote the total volumes of reported crimes $\vec{c} \cdot \vec{p}$ and $\vec{c}' \cdot \vec{p}'$, respectively. It can be shown that $x + y + z = r$. Also, $x = z = 0$ and $y = r$, when $\vec{p}' = \vec{p}$. When $\vec{c}' = \vec{c}$, it is seen that $y = z = 0$ and $x = r$.

B. Decomposition of the Percentage of Change of the Crime Volume into Two Components:

In the preceding section, the percent change in crime volume r was divided into the three components x , y , and z , where z was the cross-product component, representing the combined effect of populational and non-populational factors. Sometimes, the situation arises where z has to be appropriately split and attached to the populational and non-populational factors, so that only two components are allowed. The method described in this section is most appropriate when two years under consideration are consecutive.

A simple computation establishes that

$$D = V' - V = \left(\frac{\vec{c}' + \vec{c}}{2} \right) \cdot \Delta \vec{p} + \Delta \vec{c} \cdot \left(\frac{\vec{p}' + \vec{p}}{2} \right).$$

The vectors $\left(\frac{\vec{c}' + \vec{c}}{2} \right)$ and $\left(\frac{\vec{p}' + \vec{p}}{2} \right)$ are the crime rate vector and the population vector at the middle of two years. The term

$\left(\frac{\vec{c}' + \vec{c}}{2} \right) \cdot \Delta \vec{p}$ denotes the portion of D arising from the shift $\Delta \vec{p}$ in the population pyramid when the crime rate vector is fixed at the level of the midpoint of two years. The second term

$\Delta \vec{c} \cdot \left(\frac{\vec{p}' + \vec{p}}{2} \right)$ indicates the portion arising from the shift $\Delta \vec{c}$ of the age-specific crime rate when the population vector is held at the midpoint level $\left(\frac{\vec{p}' + \vec{p}}{2} \right)$. Define the rates of change ξ and η

$$\text{by } \begin{cases} \xi = \frac{\left(\frac{\vec{c}' + \vec{c}}{2} \right) \cdot \Delta \vec{p}}{V} \\ \eta = \frac{\Delta \vec{c} \cdot \left(\frac{\vec{p}' + \vec{p}}{2} \right)}{V} \end{cases}$$

$$\text{Then, } \xi + \eta = r$$

$$\vec{p}' = \vec{p} \text{ implies } \xi = 0 \text{ and } \eta = r$$

$$\vec{c}' = \vec{c} \text{ implies } \xi = r \text{ and } \eta = 0$$

$$\xi = x + \frac{1}{2}z$$

$$\eta = y + \frac{1}{2}z$$

$$\xi = \frac{1}{2}(r + \frac{\vec{c} \cdot \vec{p}' - \vec{c}' \cdot \vec{p}}{V})$$

$$\eta = \frac{1}{2}(r - \frac{\vec{c} \cdot \vec{p}' - \vec{c}' \cdot \vec{p}}{V}).$$

C. Comments on Other Approaches:

A few comments on other approaches are due at this juncture. One of the methods that is used to eliminate the non-populational impact from r is as follows. Let $\gamma = \sum c_j$ and $\gamma' = \sum c'_j$. It is noted that generally γ and γ' are not equal. Introduce \vec{c}_* and \vec{c}'_* by normalizations $\vec{c}_* = \langle c_j / \gamma \rangle$ and $\vec{c}'_* = \langle c'_j / \gamma' \rangle$, so that the areas under the graphs \vec{c}_* and \vec{c}'_* are one.

If one defines v_* by $(\vec{c}_* \cdot \vec{p})$ and v'_* by $(\vec{c}'_* \cdot \vec{p}')$, then v_* and v'_* no longer represent actual volumes but indicate "relative" volumes. Therefore, the rate of change $r_1 = (v'_* - v_*) / v_*$ is a meaningful quantity. When used to measure the impact of the population shift and structure upon crime, however, r_1 is problematic in many respects. This is explained below.

$$\begin{aligned}\text{Computations establish that } r_1 &= -\frac{\gamma' - \gamma}{\gamma} + \frac{\gamma}{\gamma'} r \\ &= -\frac{\gamma' - \gamma}{\gamma} + \frac{\gamma}{\gamma} (\xi + \eta).\end{aligned}$$

When the population pyramid stays stable (i.e., $\vec{p}' = \vec{p}$) and the age-specific crime rate changes by a constant factor uniformly on all ages ($c'_j = k c_j$), then $\vec{c}'_* = \vec{c}_*$ so that $r_1 = 0$. This situation makes r_1 appear plausible. In this example, the population factor has no bearing on the change of crime r . However, if the second condition $c'_j = k c_j$ is dropped from the above example, retaining the first assumption of no populational changes, it is seen that r_1 is generally non-zero (contrary to the expectation that $r_1 = 0$). The worst case is that $\vec{p}' = \vec{p}$, $\gamma' = \gamma$, and $\vec{c}'_* \neq \vec{c}_*$ where it is established that $r_1 = r$.

In summary, r_1 eliminates the impact of changes in \vec{c} related to γ , but is not capable of deleting the impact of structural

changes in \vec{c} . Redefining γ and γ' to be $\gamma = \sqrt{\sum c_j^2} = \| \vec{c} \|$ and $\gamma' = \sqrt{\sum c_j'^2} = \| \vec{c}' \|$ does not create a significant difference to the behavior of r_1 .

D. Approximation of the Age-Specific Crime Rates:

As mentioned earlier, $\vec{c} = \langle c_j \rangle$ is unknown. Therefore, age-specific arrest rate $\vec{a} = \langle a_j \rangle$ is used to approximate \vec{c} in the following manner. Let λ be defined by $V = \lambda \vec{a} \cdot \vec{p}$ (V = the total number of crimes reported) and let $c_j = \lambda a_j$. In other words, $c_j = \frac{V}{\vec{a} \cdot \vec{p}} a_j = \frac{V}{A} a_j$ with $A = \vec{a} \cdot \vec{p} = \sum a_j p_j$. When using UCR arrest data, age-specific arrest rates are given in terms of age groupings and not by single ages. This does not affect the calculation. When the crime rate vector \vec{c} is approximated by the above method, x , y , and z become as follows:

$$x = \frac{\vec{c} \cdot \Delta \vec{p}}{V} = \frac{\vec{a} \cdot \vec{p}' - \vec{a} \cdot \vec{p}}{\vec{a} \cdot \vec{p}},$$

$$y = \frac{\Delta \vec{c} \cdot \vec{p}}{V} = \frac{\mu \vec{a}' \cdot \vec{p}' - \vec{a} \cdot \vec{p}}{\vec{a} \cdot \vec{p}} \quad \text{where } \mu = \frac{V'A}{VA}, \text{ and}$$

$$z = \frac{\Delta \vec{c} \cdot \Delta \vec{p}}{V} = \frac{\mu \vec{a}' \cdot \vec{p}' - \mu \vec{a}' \cdot \vec{p} - \vec{a} \cdot \vec{p}' + \vec{a} \cdot \vec{p}}{\vec{a} \cdot \vec{p}}.$$

The ordinary rate of volume change is

$$r = \frac{V' - V}{V} = \frac{\mu \vec{a}' \cdot \vec{p}' - \vec{a} \cdot \vec{p}}{\vec{a} \cdot \vec{p}}.$$

The result of these calculations is tabulated in Table 1. Also, the rates ξ and η are expressed as

$$\xi = \frac{1}{2} r + \frac{1}{2} \frac{\vec{a} \cdot \vec{p}' - \mu \vec{a}' \cdot \vec{p}}{\vec{a} \cdot \vec{p}} \quad \text{and}$$

$$\eta = \frac{1}{2} r - \frac{1}{2} \frac{\vec{a} \cdot \vec{p}' - \mu \vec{a}' \cdot \vec{p}}{\vec{a} \cdot \vec{p}}.$$

The quantities ξ and η are indicated in Table 2.

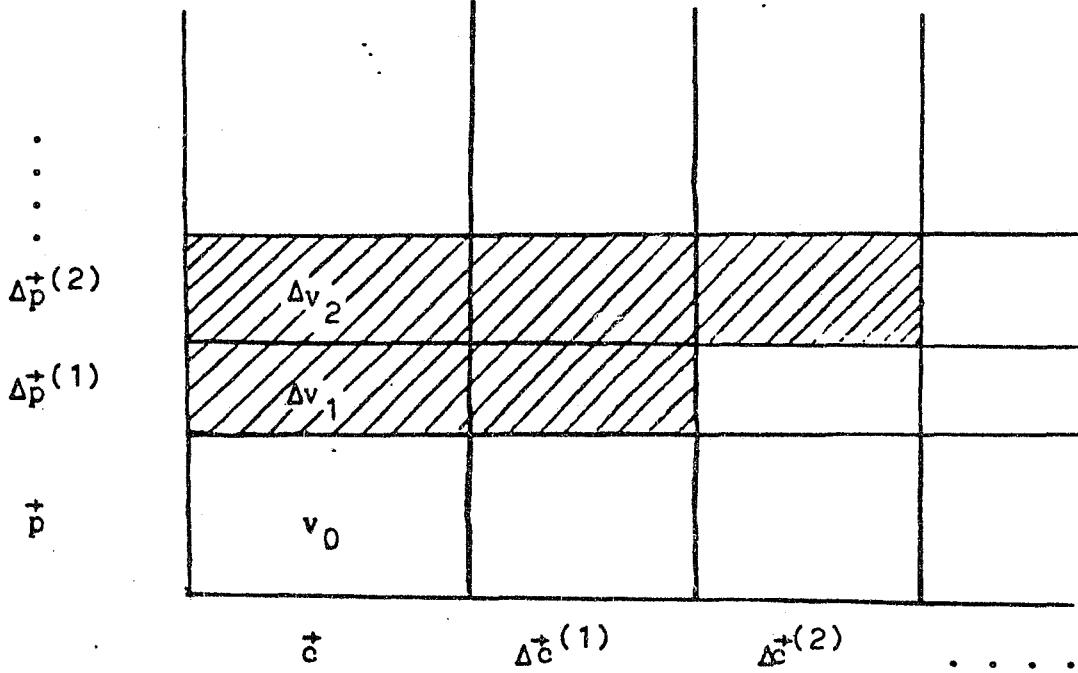

E. Chain Multiplication Property:

If r_{ik} denotes the change in crime volume from the i^{th} year to the k^{th} , $1 + r_{ik} = (1 + r_{im})(1 + r_{mk})$ holds. However, the rates introduced so far (x, y, z, ξ , and η) do not accept this chain multiplication. For example, when x_{ik} denotes the rate of change from the i^{th} year to the k^{th} , the identity

$$1 + x_{ik} = (1 + x_{im})(1 + x_{mk}) \text{ does not generally hold } (i < m < k).$$

Consider crime data associated with the years $0, 1, 2, \dots$. Let \vec{c} and \vec{p} correspond to the base year 0, and let $\Delta\vec{c}^{(n)}$ and $\Delta\vec{p}^{(n)}$ be the changes in the crime rate vector and the population vector between the $(n - 1)^{\text{st}}$ year and the n^{th} year. The crime increment arising from populational impacts from the $(n - 1)^{\text{st}}$ to the n^{th} year is defined by $\Delta v_n = (\vec{c} + \Delta\vec{c}^{(1)} + \dots + \Delta\vec{c}^{(n)}) \cdot \Delta\vec{p}^{(n)}$ where $n = 1, 2, 3, \dots$. Further, define inductively the "level" of crime v_n for the n^{th} year by $v_0 = \vec{c} \cdot \vec{p} = V$

$$v_n = v_{n-1} + \Delta v_n.$$

The rate of change between the i^{th} and the k^{th} year is $\rho_{ik} = \frac{\sum_{l=i+1}^k \Delta v_l}{v_i}$.

With this definition, ρ_{ik} 's satisfy the chain multiplicative property: $1 + \rho_{ik} = (1 + \rho_{im})(1 + \rho_{mk})$, for all i, m , and k , with $i < m < k$.

The relative values of v_n are tabulated in Table 3 by equating v_0 of the base year 100.

F. Positions of Vectors \vec{c} , \vec{p} , and \vec{p}' :

In two-year comparisons, let $\{\vec{c}, \vec{p}\}$ and $\{\vec{c}', \vec{p}'\}$ be associated with the first and the second year, respectively. It is assumed that $\vec{c}' = \vec{c}$. The rate of change in crime volume, r , is then expressed as

$$r = \frac{\vec{c} \cdot \vec{p}' - \vec{c} \cdot \vec{p}}{\vec{c} \cdot \vec{p}} = \frac{\vec{c} \cdot \Delta \vec{p}}{\vec{c} \cdot \vec{p}} = \frac{\|\vec{c}\| \cdot \|\Delta \vec{p}\| \cos \theta_2}{\|\vec{c}\| \cdot \|\vec{p}\| \cos \theta_1} = \frac{\|\Delta \vec{p}\| \cos \theta_2}{\|\vec{p}\| \cos \theta_1},$$

where $\theta_1 = \angle(\vec{c}, \vec{p})$ is the angle between the vectors \vec{c} and \vec{p} , and $\theta_2 = \angle(\vec{c}, \Delta \vec{p})$. Therefore, r depends upon the magnitudes $\|\vec{p}\|$ and $\|\Delta \vec{p}\|$ and the angles θ_1 and θ_2 , which means that \vec{p}' could be moved without changing r so that \vec{p} , \vec{p}' , and \vec{c} are coplanar. Let \vec{p}'' be the vector which satisfies the conditions:

- \vec{p}'' is coplanar with \vec{c} and \vec{p} ,
- $\|\vec{p}''\| = \|\vec{p}'\|$, and
- $\angle(\vec{c}, \vec{p}'') = \angle(\vec{c}, \vec{p}')$.

Such a vector \vec{p}'' may be found by writing a linear combination $\vec{p}'' = t\vec{c} + s\vec{p}$, and then solving the equations $\|\vec{p}'\| = \|\vec{c} + s\vec{p}\|$ and $\vec{c} \cdot \vec{p}'' = \vec{c} \cdot (t\vec{c} + s\vec{p})$ for t and s , i.e.,

$$\begin{cases} \|\vec{p}'\|^2 = t^2 \|\vec{c}\|^2 + 2ts(\vec{c} \cdot \vec{p}) + s^2 \|\vec{p}\|^2 \\ \vec{c} \cdot \vec{p}'' = t \|\vec{c}\|^2 + s(\vec{c} \cdot \vec{p}). \end{cases}$$

G. Upper and Lower Limits of the Populational Impact:

It is recalled that \vec{c} is not empirically known. Approximation of \vec{c} using \vec{a} could be a moot issue. In the sequel, therefore, a method of finding the crime rate vectors that maximize/minimize the populational effect x is discussed. This issue is equivalent to the following linear programming problem:

Choose a vector \vec{t} to maximize/minimize $D = \vec{c} \cdot \vec{\Delta p}$ under the constraints that $V = \vec{t} \cdot \vec{p}$ and $\vec{t} \geq \vec{0}$.

Since the constraint set is a simplex, maximum/minimum solutions occur at a vertex of the simplex. Vertices are given by $\vec{t} = \langle c_j \rangle$ where $c_j = \delta_{ij} V/p_i$ where δ_{ij} is the Kronecker's delta. Then, $D = \vec{c} \cdot \vec{\Delta p} = \sum_j \delta_{ij} V(\Delta p_j)/p_i = V(\Delta p_i)/p_i$. Therefore, by noting that $x = D/V$, it is seen that $\min_i \{\Delta p_i/p_i\} \leq x \leq \max_i \{\Delta p_i/p_i\}$.

The vector \vec{c}_{\max} that maximizes x is of the form

$\vec{c}_{\max} = \langle \delta_{kj} V/p_k \rangle$ for some k such that $\Delta p_k/p_k \geq \Delta p_i/p_i$ for all i .

Likewise, the vector \vec{c}_{\min} that minimizes x is of the form

$\vec{c}_{\min} = \langle \delta_{\ell j} V/p_\ell \rangle$ for some ℓ such that $\Delta p_\ell/p_\ell \leq \Delta p_i/p_i$ for all i .

The upper limit ($\vec{c}_{\max} \cdot \vec{\Delta p}/V$) and the lower limit ($\vec{c}_{\min} \cdot \vec{\Delta p}/V$) of x are tabulated in Table 4. These limits are independent of crime categories.

It should be noted that all values of x (Table 1) fall between the lower and upper limit figures (Table 4), i.e., the limits represent mathematical bounds for populational effects. However, these bounds are highly unrealistic in that they depend only on population vectors and not on the realistic assessment of age-specific crime rates. It is important to note that the rates of change in crime volume (r) frequently fall out of intervals specified by these bounds.

H. Splitting the Populational Effect x into the Components of Population Size and Age Composition

It will be remembered that the rate expressed by x represents the effect of population on changes in the volume of crime. When $\Delta\vec{p}$ is examined, it is noted that the populational effect possesses two elements, one arising from changes in population size and the other derived from shifts in age composition.

Recall that $x = (\vec{c} \cdot \Delta\vec{p}) / (\vec{c} \cdot \vec{p})$, where $\Delta\vec{p} = \vec{p}' - \vec{p}$. Let $P = \sum p_j$ and $P' = \sum p'_j$: P and P' denote total populations for the first and the second year. Since $(\vec{c} \cdot \vec{p})/P$ represents the overall crime rate for the first year, the expected volume of crime for the second year should be $P'(\vec{c} \cdot \vec{p})/P$ if no structural changes in the population took place. (It is noted that \vec{c} is held constant).

$$\text{Let } x_1 = \frac{\vec{c} \cdot \vec{p}' - P'(\vec{c} \cdot \vec{p})/P}{\vec{c} \cdot \vec{p}} .$$

$$\text{Then, } x_2 = x - x_1 = \frac{P' - P}{P} .$$

The quantity x_1 represents changes in the volume of crime that are caused by shifts in populational structure (age composition) and x_2 represents changes that result from shifts in total population size. These two components x_1 and x_2 add to x by construction. The impact of the passing "baby boom" generation primarily belongs to the measurement x_1 .

I. Conclusion

The configurations of age-specific arrest rates differ substantially from one crime category to another, as do the configurations of age-specific crime rates that are approximated through arrest data. In spite of the wide differences in age-specific crime rates, the short-range impact of populational factors was observed to be "small" throughout the seven Index crimes studied.

The shift in the age composition of the United States population, particularly the reduction in the crime-prone segment, has resulted in a minor crime decline (robbery, burglary, larceny-theft and motor vehicle theft) or toward a reduced rate of increase (murder, forcible rape, and aggravated assault). See Tables 1 and 2. It should also be noted that the combined effect of populational and non-populational factors is negligible (Table 1).

When the actual volume of crime was compared, over the period 1978-1983, with hypothetical trends generated solely through the impact of populational shifts, it was found that these curves were highly discrepant, indicating that non-populational factors were primarily responsible for the crime increase in the late 1970's and the decline in most recent years. See Table 3 and the graphs following Table 3.

In order to represent the maximum possible impact that population could exert on the volume of crime, upper and lower bounds can be computed. During the last six years, 1978-1983, the crime volume changes experienced often exceeded these limits, thus indicating the relatively minor impact of population on crime. See Table 4.

MURDER, 1978-1983

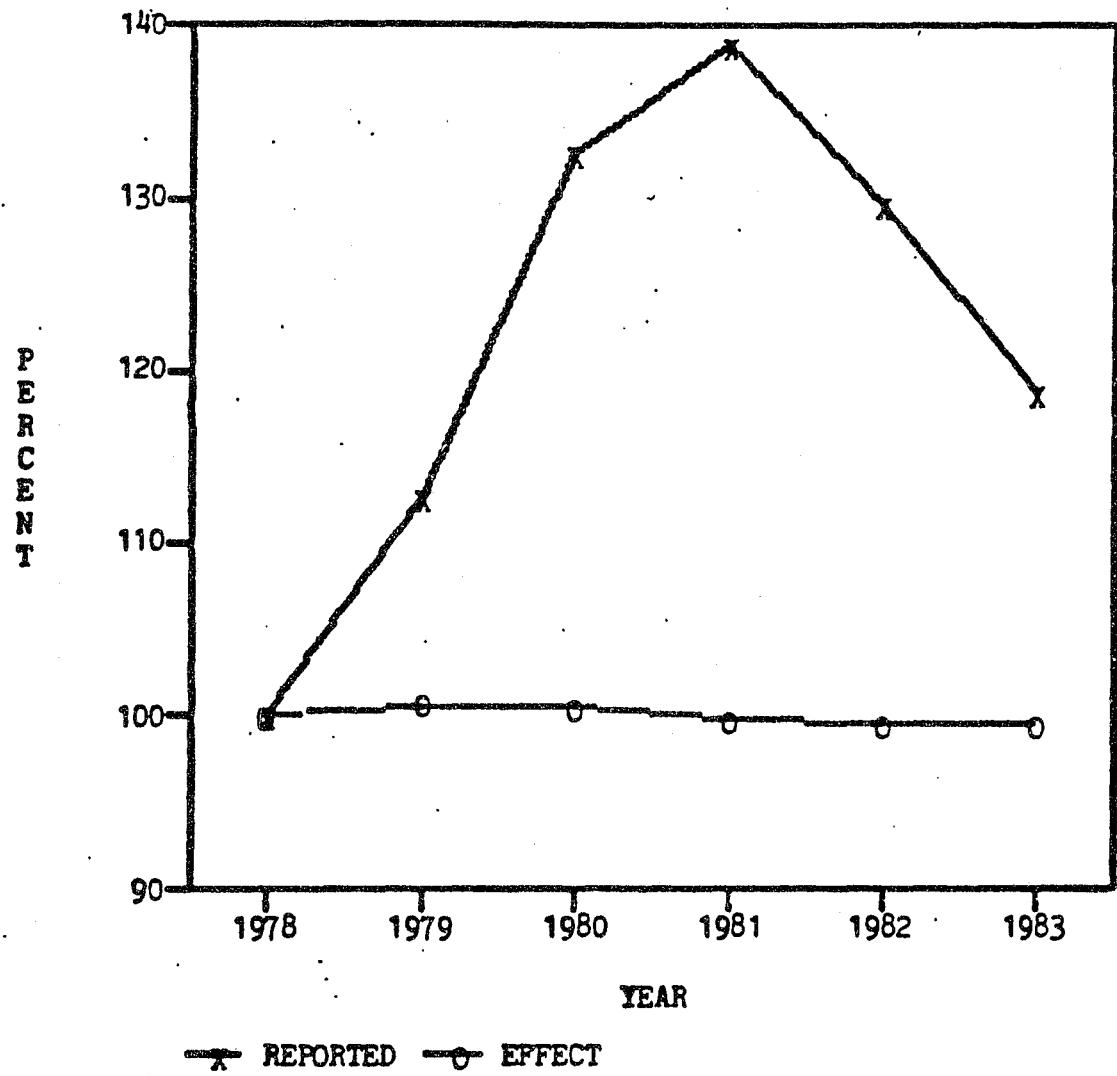

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

FORCIBLE RAPE, 1978-1983

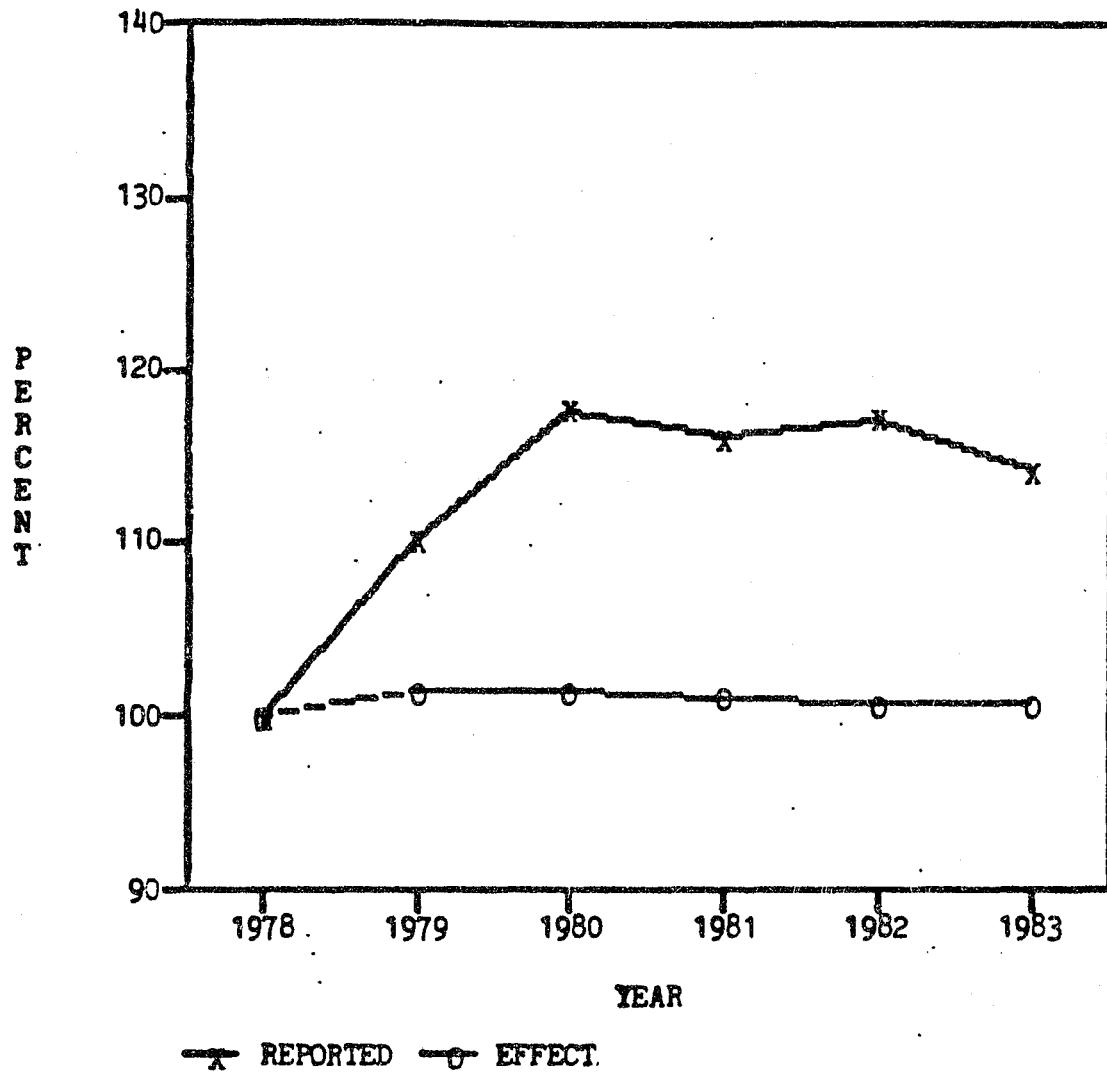

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

ROBBERY, 1978-1983

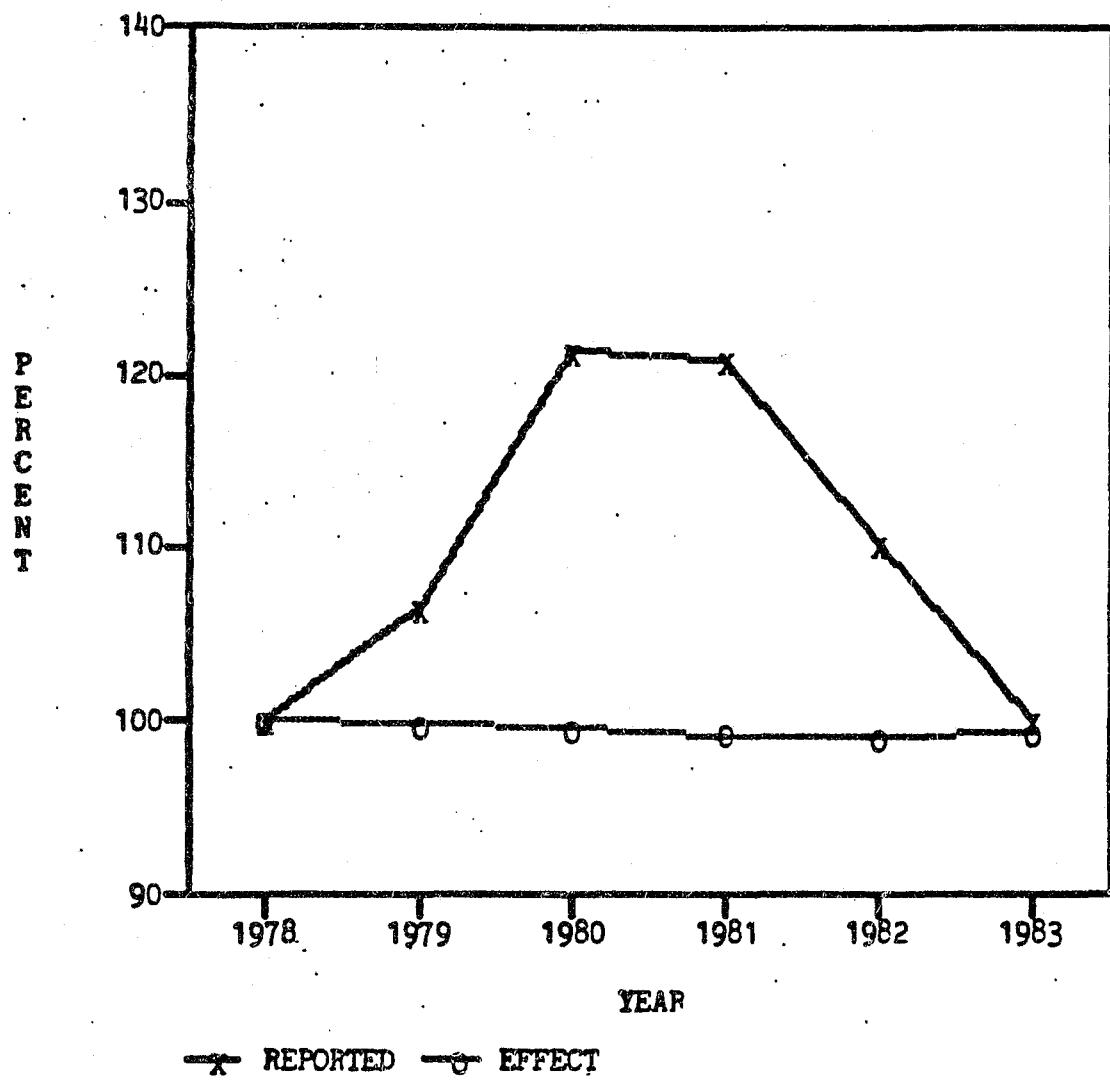

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

AGGRAVATED ASSAULT, 1978-1983

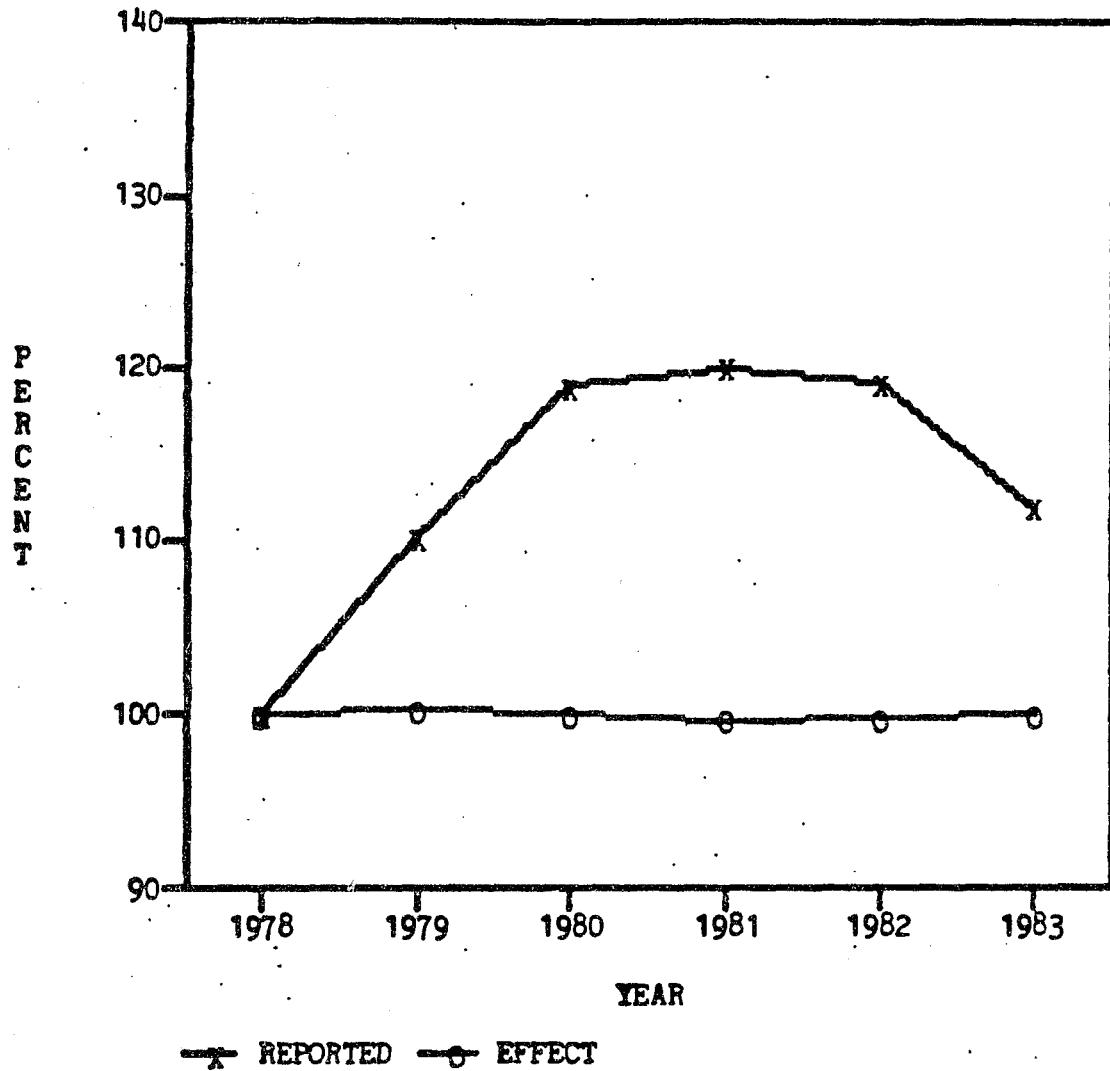

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

BURGLARY, 1978-1983

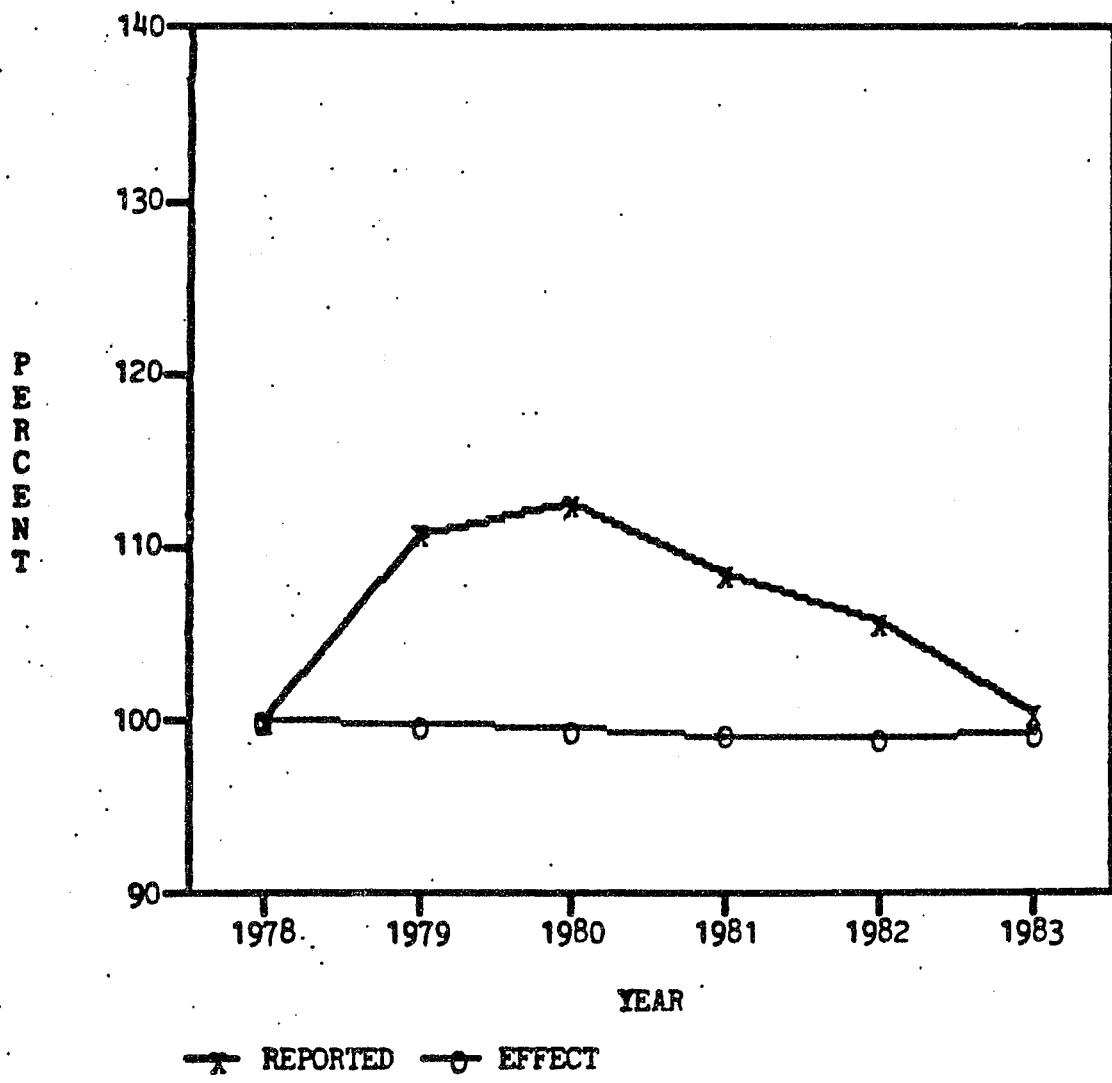

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

LARCENY-THEFT, 1978-1983

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

MOTOR VEHICLE THEFT, 1978-1983

The curve labeled "reported" represents the estimated volume of reported crimes. The curve labeled "effect" shows the hypothetical changes in the crime volume that would have occurred solely from populational shifts. Both curves are standardized by equating the 1978 figures to 100.

TABLE 4
 Percentages of the Upper and Lower Limits of
 Populational Effects

	LOWER LIMIT	UPPER LIMIT
1979 over 1978	-4.6%	+4.6%
1980 over 1979	-4.0	+4.7
1981 over 1980	-5.9	+5.6
1982 over 1981	-5.9	+8.6
1983 over 1982	-5.9	+5.7

Note: Limits were computed using the UCR age groupings.

Age Groups at Which Maximums and Minimums of $(\Delta p_1/p_1)$
 Were Achieved

	MINIMUM	MAXIMUM
1979 over 1978	13 - 14	30 - 34
1980 over 1979	15	30 - 34
1981 over 1980	15	30 - 34
1982 over 1981	16	35 - 39
1983 over 1982	16	35 - 39

APPENDICES

Appendix A Data Source and Definitions

Data utilized in this publication were obtained from the Uniform Crime Reporting (UCR) Program, the U.S. Bureau of the Census, the Bureau of Labor Statistics, and the Department of Transportation.

Various starting years (1965, 1973, 1974, 1976) in Part I Tables were determined through data availability. UCR data as related to this report has undergone the following historical changes:

1. With respect to rape, the categorical breakdowns of forcible rape and attempted forcible rape were first collected in 1964.
2. The inception of robbery breakdowns according to weapon occurred in 1974.
3. The weapon breakdown for aggravated assault was initiated in 1964.
4. Burglary breakdowns (forcible entry, unlawful entry, and attempted forcible entry) were introduced in 1964.
5. Burglary breakdowns by time of day were collected from all contributing agencies beginning in 1972.
6. Motor vehicle theft breakdowns, according to type of vehicle, originated in 1974.

The source of population data is the Current Population Reports series as listed below:

1965 - 1969	Series P-25, No. 519
1970 - 1979	Series P-25, No. 917
1980 - 1982	Series P-25, No. 929
1983	Series P-25, No. 949
1984	Series P-25, No. 965

The Statistical Abstract of the United States, 1973-1985 provided the household data used to compute burglary population-at-risk rates. The Statistical Abstract defines a household as consisting of:

"all persons who occupy a housing unit where a housing unit is a house, an apartment, or other group of rooms, or a single room that constitutes separate living quarters."

The consumer price index, published by the Bureau of Labor Statistics, measures the average change in prices over time for a fixed market basket of goods and services. These figures were used to compute the average monetary loss per larceny-theft. With regard to Table 68, the constant dollars refer to the values for which the effect of price changes have been eliminated through the application of price indices. Also stated are current dollars which reflect the prices prevailing at a specified time.

The number of motor vehicle registrations, published by the Department of Transportation(DOT), was used to compute the population-at-risk rates of motor vehicle thefts. The categorical breakdown per DOT data, is auto, trucks and buses, all other vehicles and motorcycles. UCR breakdown is auto, trucks and buses, and other vehicles. Therefore, only the "auto" and "trucks and buses" categories are presented in Tables 73, 74, and 75.

All computations throughout this publication were achieved through unrounded figures. For example, percent changes in rate were calculated from unrounded rate figures. Therefore, using rounded rates may not give the same percent changes as tabulated in this report.

Appendix B
Table Methodology

The probabilities of "lifetime" murder victimization presented in Tables 24, 25, and 26 were computed by the following method. For a given race and sex category, let S_i be the number of survivors, out of 100,000 newly born babies, at their i^{th} birthday. $S_0 = 100,000$. It is assumed for the sake of simplicity and compatibility with UCR data that $S_{100} = 0$. The ratio $r_i = S_i/S_0$ represents the survival rate. Let V_i denote the annual murder victimization rate (based, in this report, on 1984 UCR murder data) expressed per 100,000 inhabitants who are age i and belong to a particular race and sex category. Then, for this segment of the population, the number of murders between the i^{th} birthday and the $(i + 1)^{\text{st}}$ birthday is given by $M_i = V_i r_i$. For a person age i , then, the probability P_i of being a murder victim for the remainder of his/her lifetime is $P_i = \left(\sum_{k=i}^{100} M_k \right) / S_i$. The above probability figures P_i are shown in Tables 24, 25, and 26 in the "1 out of ..." format.

In Table 27, the hypothetical prolongation of the lifespan is computed for each race and sex. This table depicts the reduction of life expectation due to murder. Using the same notation as before, the survivors (S_i) at their i^{th} birthday fall into one of the following three groups:

- a. Surviving at their $(i + 1)^{\text{st}}$ birthday: S_{i+1} .
- b. Murdered by their $(i + 1)^{\text{st}}$ birthday: $M_i = V_i r_i$.
- c. Deceased due to causes other than murder by their $(i + 1)^{\text{st}}$ birthday: $D_i = S_i - S_{i+1} - M_i$.

Let S_i denote the hypothetical number of survivors at the i^{th} birthday under the assumption that no murders take place. \hat{S}_i is greater than S_i except when $i = 0$ where $\hat{S}_0 = S_0 = 100,000$. As before, $\hat{r}_i = \hat{S}_i/\hat{S}_0 = \hat{S}_i/100,000$ is the hypothetical survival rate at age i . \hat{S}_i 's are computed from the relationship

$$\hat{S}_{i+1} = \frac{S_{i+1}}{S_i - M_i} \hat{S}_i, i = 0, 1, 2, 3, \dots$$

A survival rate curve would in reality be represented by a smooth function defined for age $x \geq 0$. Let $g(x) = -f'(x)$. Since $\int_a^b g(x)dx = f(a) - f(b)$, $g(x)$ may be viewed as a death distribution function. Furthermore, since $\int_0^\infty f(x)dx = \int_0^\infty xg(x)dx$ (integration by parts), the area under the survival rate curve $f(x)$ represents the life expectation. Therefore, the actual life expectation is

$$h \doteq \frac{1}{2}(r_0 + r_1) + \frac{1}{2}(r_1 + r_2) + \dots$$

$$= \frac{1}{2} + r_1 + r_2 + r_3 + \dots$$

Similarly, the life expectation under the assumption of no murders is $\hat{h} \doteq \frac{1}{2} + \hat{r}_1 + \hat{r}_2 + \hat{r}_3 + \dots$. For each race and sex category, the difference in two life expectations
 $\hat{h} - h \doteq (\hat{r}_1 - r_1) + (\hat{r}_2 - r_2) + (\hat{r}_3 - r_3) + \dots$ is tabulated in Table 27 using months as the unit of count.
